The idea, prevalent in some quarters, that Latin is dying out in our high schools is not warranted by the statistics in the reports of the Commissioner of Education. This idea is supported at first glance by the declining percentages, shown in the first column of the table reproduced below, of public high school students who are studying Latin. The number of students in Latin courses, however, has continued to increase, as can be seen from the right-hand column.

Percentages of the High School Population and the Number of Students Studying Latin (1910-34)

	Per Cent	Number
1910	49.05	362,548
1915	37.32	434,925
1922	27.52	593,086
1928	21.99	636,952
1934	16.04	721,320

The apparent discrepancy between the two columns above is explained by the fact that although the number studying Latin has steadily increased, the total high school population has increased much more rapidly. An

interesting fact to be noted is that while, with the increase in high school attendance, many new subjects have been added to the curriculum, nevertheless the number of students taking Latin has increased.

LEADERSHIP TRAINING. Leadership training may be defined as a conscious effort in an educational agency to develop in pupils believed to have leadership potentialities those qualities found to be associated with leadership. This effort has been stimulated in recent years by research showing what qualities are associated with demonstrated leadership, by research purporting to show that these qualities are educable, and by a growing conviction that the success of democratically governed enterprises depends upon capable leadership. Qualities found to be associated with leadership include high intelligence, initiative, courage, self-reliance, kindness, tact, fairness, energy, and the like. It has been demonstrated that pupils placed in positions of leadership grow in these qualities, their development being more rapid than that of the other pupils. Emphasis in leadership training in the school has been upon participation in school activities. Especially, it has been urged that student self-government plans both train and identify leaders. Segregation of potential school leaders in special classes has generally been abandoned. Special courses for leaders have had some vogue. A more common practice is that of discussing leadership in home rooms or in special orientation or personal development

classes. There are many published manuals for such discussion groups which contain units on leadership. "Leaders Clubs" have been employed in some schools both to honor and to train student leaders.

Leadership training has a special meaning in religious education, referring to the training of church school teachers, supervisors, and administrators.

LEARNING. Some of the controversies which arise in an attempt to explain learning may be owing to the fact that it is impossible to give a single descriptive definition of learning. There is little similarity among the processes of learning a poem, mastering the ability to divide a number by another number, learning to like a disliked food, learning to waltz, learning that a certain sound means an airplane is approaching from the west, learning how to get along with neighbors, learning the shortcuts to the railway station, gaining an understanding of Plato's philosophy, etc. Nor is the resultant of the learning in each of these cases the same. The common feature is that in every instance some change has occurred in the individual. He now can do what he previously could not do.

Explanations of how these changes are brought about are made on different levels. The practical man usually asks how certain learnings can be brought about, or brought about in a shorter time, or brought about more effectively. When he asks, "How do we learn?" he wants an explanation in terms of rules which will tell him how to arrange the factors in the environment or what method of attack the learner should use. Answers cannot be supplied him, however (except as he can be told that in a particular type of situation this specifically described method brings better results than that specifically described method), without theoretic explanations of how learning takes place being used as a matrix for making deductions and for generalizing principles.

Explanations of how learning takes place have been couched in metaphysical, physi-

LEARNING

ological, and psychological terms or in some combination of these. Every school of philosophy and every school of psychology involves some theory of learning. Bode, who combines the disciplines of philosophy and psychology, contrasts learning theories on the basis of their conception of the relation between "mind and body". He distinguishes various schools of thought: (1) schools of thought which hold to a complete dualism of mind and body and make the mind alone responsible for all knowledge, (2) schools of thought (e.g., *structuralism*) which accept the dualism but which postulate that though there is no connection between mind and body, changes in one, as learning takes place, parallel changes in the other, (3) schools of thought (e.g., *behaviorism*) which deny the existence of mind altogether and attempt to explain learning on the basis of specific physiological changes only, and (4) schools of thought (e.g., *functionalism*, *pragmatism*), which grant mind an "emergent" status, and therefore deny that learning ever can be explained in purely physiological (or neural) terms, even though learning always has a physiological base.

The physiological explanation of learning has occupied the attention both of those who accept the theory of mind as an emergent in the evolutionary process and of those who deny the existence of mind. Most of the physiological theories are neurological explanations. Unfortunately, findings derived by neurologists in this study of the nervous system (*q.v.*) sometimes are expanded by psychologists into theories which in the end have little experimental evidence to support them. Such almost purely hypothetical neurological explanations, framed originally to bolster a psychological theory of learning, may in turn force the psychological theory into channels from which extrication becomes difficult even when observation of behavior demands it. It must be kept in mind that direct study of the nervous system may bring forth descriptions of its functioning that are reliable but from which principles of learning cannot be deduced. On the other hand, certain kinds of physiological experiments contribute directly to the proof or disproof of psychological theories. The work of Lashley, Sherrington, and Child, for example, contribute data which are valuable for resolving the

controversy between the defenders of the atomistic and the defenders of the holistic theories of learning. When Lashley's surgical operations on animals showed that specific learnings were not localized in specific brain pathways, the synaptic theory of neurone connections could no longer be used to bolster the psychological theory that all learning consists of the building of specific connections between stimulus and response through the process of repetition that stamps these connections into the brain.

Other neurological findings are useful not because they tell us what happens to the nervous system when learning takes place but because they indicate conditions that prevent learning from taking place. Improvement of our knowledge of the organic foundations of intelligent behavior may lead eventually to better formulations of principles of learning. At present, however, most principles of learning depend almost completely upon observation of behavior and very little upon study of the nervous system.

Besides differing in their conceptions of the neural basis of learning, theories of learning differ in many other respects. Some of the principal areas of controversy are those respecting motivation, the amount of insight necessary for learning to take place, the place of repetition in learning, principles of remembering and forgetting, the relation of words to learning, and transfer of learning. Some principles of learning are stated in such a way that they cannot be translated into principles for guiding the learning process. Others clearly imply a technique of education, and these are seized upon and used irrespective of the modifications which their author intended his other principles—unfortunately pragmatically meaningless—to have upon them. Of Thorndike's three famous laws of learning, for instance, laws which were meant to be used in relation to each other, it was the law of exercise and, to a lesser extent, the law of effect that were translated into educational practice, while the law of readiness was disregarded. The law of exercise, which stated that the vigor and duration of the making of a connection as well as the number of times that it is made determine the strength of the connection, was taken to mean that repetition was the keynote of learning. The law of effect stated that when the

making of the connection was accompanied or followed by a satisfying state of affairs the strength of the connection is increased, and that when accompanied or followed by an annoying state of affairs the strength of the connection is decreased. This law pointed clearly enough to the use of rewards and punishments in the teaching process. The third law, the law of readiness, stated that when any conduction unit was in readiness to conduct, to do so was satisfying, while not to do so was annoying. Conversely, when a conduction unit which was not ready to conduct was made to do so, annoyance was the result. The law as stated gives no answer to the question of when conduction units are ready to conduct. Educators who tried to base their teaching on Thorndike's three laws of learning often disregarded completely the law of readiness. Otherwise, they translated it so as to embody some meaning of readiness which they already had. Commonly, readiness has been taken to mean mental-set, and mental-set has been correlated with purpose, motive, or goal.

The tendency for educators to be eclectic in the principles of learning which they adopt, that is, to choose principles deriving from different schools of psychology, probably arises both from the fact that no school has set forth a sufficient number of learning principles that have clear-cut pedagogical implications (sufficient, that is, upon which to base procedures in the various learning areas with which the school is concerned), and from the fact that what look like different principles to different psychologists appear to lead to the same educational practices. (For a discussion of learning theories in terms of schools of psychology the reader is referred to *PSYCHOLOGY, SCHOOLS OF*. In the present article learning will be discussed in terms of the problems facing the educator.)

One of the primary pedagogical questions is whether the learner needs to purpose to learn before he does learn. Can he learn without intent? If so, how effective is such learning? If the desire and intent to learn bring better learning, how can such desire be aroused when it is not already present? That we learn certain things without intending to do so has been recognized sufficiently for the process to be termed *incidental learning*, *concomitant learning*, or *collateral learning*.

Incidental learnings are acquired during the course of pursuing some end, but they themselves do not contribute directly to the attainment of that end. Most likes, dislikes, emotional attitudes, and mannerisms are attained without conscious intent and even in spite of intent to the contrary. They are explained variously in terms of conditioning, of repetition, and of subconscious or even unconscious purposes. It is widely agreed that while complex skills cannot be attained without deliberate intent, attitudes and emotional habits in the majority of cases develop incidentally and are even difficult to attain by deliberate effort. For the educator, this means that all situations must be examined critically to find what concomitant learnings they favor and how they may be changed to increase the chances of bringing about desirable incidental learnings. (See *LEARNINGS, SIMULTANEOUS*.) It means also that where complex skills and understandings, and systematic, precise facts are to be learned, incidental learning cannot be depended on.

Functional learning has been distinguished from incidental learning, functional learning being that which is necessary to achieve one's ends but which is itself not the starting goal of the activity. Thus children may learn to use a yardstick when they measure windows for the curtains they wish to buy for their classroom. There is a good deal of controversy as to how effective are such functional learnings when they are not separated from the gross activity in which they arise and when they are not given deliberate attention on their own account. As with incidental learning, a great deal probably depends upon how complex is the subject matter that has been used functionally but that has not been set-out-to-be learned, and how much repetition is necessary to master it. An important growing agreement is that the best introduction to subject matter is through its functional use and that some functional learning should precede all formal study.

Whether extrinsic motivation is as effective as intrinsic motivation is hotly debated. Thorndike's latest work on incentives (*q.v.*) still leads him to the conclusion that rewards which have no direct connection with the subject matter being learned are almost as effective as intrinsic interest. Others who disagree vigorously point out that Thorndike

LEARNING

deals largely with the memorization of verbal material and that much greater differences might be found if different learning tasks were studied. (See MOTIVATION.)

There is still some, though increasingly less, debate as to whether rewards act as goals serving to direct behavior toward attainment, or whether they merely reinforce the response to which the reward is attached, so that that response is more likely to occur in the future. Those who hold that every response is goal-directed are also ready to accept the fact that individuals will tend to repeat behavior for which they received unexpected rewards. They merely add the interpretation that when that behavior is repeated it is done with the expectancy of a reward and is therefore goal-directed, though not toward the same goal as when first produced. How greatly recall is improved when an unexpected, pleasant state of affairs is added to the end of a study period is not clear, but certain of Thorndike's studies lead one to the conclusion that with some kinds of learnings such an effect does occur.

Another pedagogical question of primary concern to all educators is the query as to what the learner should do so that his learning should progress. This question necessarily involves the problem of the organization of the subject matter the learner is to master. Should this subject matter be arranged in such a way that the responses required of the student are simple enough for him to be able to perform almost immediately, necessitating only repetition on his part for the purpose of fixing the response (that is, making it easily recallable), or should subject matter be learned in terms of problem-situations, necessitating the creation of a solution on the part of the learner? Should the learner be allowed to commit errors or should he be given the pattern and the directions for solving the problem? Since so large a proportion of experiments in human learning have dealt with the memorization of meaningless material or of isolated verbal facts or of lines of poetry, they throw little light on this problem. Some educators answer it with the matter-of-fact statement that one of the aims of the school is to teach students how to solve problems, and not only to teach them the solutions to problems. They therefore discount the value of experiments that seek to

compare how quickly solutions are learned when a large degree of guidance is given and when little or no guidance is forthcoming. They are interested more in determining what types of guidance in the solution of specific problems will increase problem-solving ability, if not in general at least in a broad area of subject matter. Some rather widely accepted hypotheses for such guidance are (1) that the problems set before the learner or the problems which he encounters and which he is encouraged to solve should be so related to the level of his understanding that he need not proceed by random trial and error, (2) that any general systematic methods for proceeding which are taught the student should be such as are suitable to his intellectual level and not those that are used by experts in the field, (3) that the student be taught to use his errors as clues for further hypotheses, (4) that the student must attain certain facts and general principles in a subject area before he can solve problems in that area.

The old theory that every response one makes is directly stamped into the brain led psychologists to warn educators that pupils must not be allowed to make errors, since if they made an error even once there would be a tendency for them to repeat that error. This led to the practice of requiring children to learn by imitating closely the pattern which the teacher set. Careful count of each response that animals made in maze learning or in getting out of problem boxes showed that the response which they finally retained was the one which led them successfully to the goal and not the one which they repeated most often. Analyses of such experiments have led to the conclusion that one remembers what not to do as well as remembering what one should do to be successful in a situation. Students may be allowed to make errors; they will not retain them if the goal toward which they are working is clear enough to them so that they know which of their responses are correct responses leading them to the goal, and which are wrong responses, not leading to the goal.

Since so much of learning is not problem-solving, as that is ordinarily defined, the question arises as to how the student should proceed with factual material and in what way factual material should be organized for him.

Gestalt psychologists and others propose that whenever possible even factual material should be presented in the nature of a problem. Since many facts may be inferred from other facts when these are known, it is suggested that the subject-matter of the curriculum be so organized that the students will have an opportunity to make such inferences. It is not suggested that this organization of known facts and the inferring therefrom of a new fact or principle replace repetition as a method of learning. It is emphasized that repetition has a place in most learning but its place is rarely at the beginning of the learning procedure. First must come the attempt to relate facts, to understand them in their relations, to gain "meanings". The drill which the learner gives himself after he has gained such understanding will be much more effective than drill which is used from the outset of the learning period.

How the learner should distribute his learning time cannot be answered except in terms of the nature of the material or process he is learning and the method of learning that he uses. Data which were gathered in experiments dealing with *distributed repetition* cannot be used to draw conclusions for the optimum length of learning periods where drill will not be the sole method of learning. However, two criteria have emerged which seem to hold with regard to the length and distribution of practice periods, no matter what the subject of learning and what the learning method used. The first of these criteria is that when fatigue (*q.v.*) sets in the efficiency of learning declines. The second is that the human organism seems to need time to learn. This may be interpreted as meaning that the nervous system needs time to integrate the changes which learning brings about. It may also mean that spread of time is beneficial because this gives the learner an opportunity to make all sorts of incidental connections between the new learnings and what he already knows, and the more connections learnings have the better are they remembered. These interpretations, both of which may be true, support the empirical findings that, in general, learning proceeds better when study periods are distributed rather than massed closely together.

The problem of the optimum length of each learning period cannot be settled except as

there is a decision as to what is the best unit of learning. This latter problem commonly is stated as the whole-part problem in learning. Like most questions asked in terms of a dichotomy it is erroneously stated. The question is not whether one should study the whole thing at one time or divide it into parts to be studied separately. Some wholes are so large that they cannot be encompassed at one time even if the learning period is several hours in length. The emphasis on the whole, or the gestalt, does indicate, however, that subject matter should be so organized that the parts into which it is divided have sufficient meaning in themselves to be able to stand alone. Moreover, the gestalt principle that learning proceeds from a vague conception of the whole to a clear view of the details and an understanding of their relationships means that the unit of learning need not be so simple that it can be grasped fully during a single learning period. When complex units are selected, the learning periods succeeding the initial one cannot be drill periods. There is repetition in that the learner meets the situation again, but he now views it from different angles and sees new meanings in it.

How far learning can be done in terms of words and yet be applied in situations where more than the recall of the words is necessary is another problem which has received study. At one time the verbal learning of rules, principles, and directions occupied the major part of the pupil's school day. Educators failed to take account of the fact that even when verbal directions for doing something are directly in front of one and do not have to be remembered, they are often difficult to follow in performance. That one learns to do by doing is now an accepted principle, though not fully adhered to in all schools.

How much one can learn to *understand* without doing and experiencing is a related question. Here Dewey's emphasis on the relationship between experience and education has done more to influence present thinking on the subject than has any school of psychology. It is now generally accepted that some direct experience is necessary as a foundation for verbal meanings. One of the distinguishing features which mark progressive educators is their belief that a good deal of such experience is necessary and that verbal meanings built upon a thin base of experiences tend to

LEARNING, CURVE OF

be faulty. It is held that related experiences must be brought to the printed pages for it to be understood and only then can further meanings be built up from the verbal material. Investigations as to the effectiveness of the radio as a learning medium indicate clearly that although the radio has an appeal for children, a good deal of what they hear puzzles them or gives them erroneous ideas. The fact that a radio program has dramatic interest does not change its verbal character.

The involved relationship between verbal understanding and practical understanding brings difficulties to the measurement of learning progress. Shall a child be given credit for "knowing" when he recognizes a verbal fact as being true when it is true, and as being false when it is false? This will be difficult to do if the findings of one study should prove to be general, findings which showed that children who could match accurately the names of geometric forms with their verbal descriptions could not identify these forms when they were drawn on a plane surface. Before curves of learning (See LEARNING, CURVE OF) can be investigated, what is meant by learning in each instance must be defined. (See CHILD PSYCHOLOGY, EDUCATIONAL PSYCHOLOGY, INCENTIVES, MOTIVATION, SCHOOLS OF PSYCHOLOGY, TRANSFER OF TRAINING.)

LEARNING, CURVE OF. The progress of learning may be portrayed graphically by a learning curve. When plotting a learning curve, the vertical axis usually represents degrees of learning as measured in such units as the number of words read in one minute, the number of examples done correctly, the score on a standardized vocabulary test, or any convenient measure appropriate to the kind of learning being investigated. The horizontal axis usually represents the number of practice sessions, or the lapse of time as measured in days, weeks, months, etc. If we were to plot the curve of learning for a student who is learning to typewrite, for example, we could measure the number of letter strokes made per minute in tests conducted at weekly intervals. After these scores have been plotted on the graph and the points connected in succession by a series of straight lines, the resulting graph is the student's learning curve.

All attempts to establish a typical curve of learning have failed. The curve of learning is neither typical for an individual nor for a specific task to be mastered. When curves of learning are drawn to represent the progress of an individual learner, many fluctuations rather than steady improvement are in evidence. It is only when the curve represents the average improvement of a group that it becomes smooth. While it is difficult to account for regressions in learning, it is important to take the universal fact of temporary regression into account when evaluating the progress of a student. No student should be told that each of his trials is expected to be better than his last.

Before curves of learning can be drawn, there must be a clear definition as to what improvement implies. Improvement may be measured in terms of the speed with which the task is completed or the number of wrong moves made before the correct solution is accomplished, or the number of errors made in a task consisting of uniform subtasks, or in terms of the age or grade or percentile norm reached on standardized tests. Some of these measures can be applied frequently, thus allowing a curve of learning to be drawn which represents only a short space of time. Others can be applied only at comparatively long intervals. The length of time between

each testing affects the shape of the curve of progress.

In many cases, learning curves have been found to be negatively accelerated. In such situations the rate of learning is greatest in the initial stages with a gradual diminution in rate as the learning proceeds. Speed curves usually show such negative acceleration. The question has often been asked as to whether there is a final level or limit to learning. Certainly improvement often reaches a limit but it is not easy to tell whether this is a real physiological limit or whether it is a plateau above which, in time, improvement again may rise.

A plateau is a period during which there is no evidence of progress in learning. Progress may be actually or only apparently arrested. Lagging interest or motivation, satisfaction with the present level of achievement, or a particularly difficult phase of the material may account for the plateau. It is thought also that a plateau in the learning curve sometimes represents a period for consolidation, organization, and assimilation of past learnings. In such cases time will bring again a rise in the curve. When a plateau persists, new motivation or a new method of teaching or learning may end it and even bring a sudden acceleration of progress.

Initial and end spurts in the curve of learning also have been found. Initial spurts are easily explainable in terms of the strong motivation often present at the beginning of a learning task and also in terms of the use of past learnings that are applicable to the new task. End spurts, by no means typical of learning curves, sometimes occur when the learner knows he is ending his learning periods. Such spurts are caused probably by the desire to make the final showing as good as possible. Sharp rises in the midst of the learning curve sometimes are owing to insight or the sudden understanding of the solution to the problem.

Learning curves are merely descriptions of progress that has already taken place, rather than being predictive of progress to be expected. Nevertheless they are useful both to the learner and to his teacher. Time and again a knowledge of results has been found to be an effective incentive. The learner, when not satisfied with his progress as shown by his learning curve, may proceed to di-

agnose his difficulties. His teacher will aid in such diagnosis as well as give help in overcoming the difficulties. The teacher may also introduce factors to increase the learner's motivation. In some subject matters, however, where each task is different from the previous one, it may be unwise to reduce the quality of each to a common factor which can be measured clearly enough to produce a curve of progress. The measurement and comparison of the common factor may emphasize it at the expense of the other factors involved in the quality of each of the tasks. The greatest abuse of the learning curve on the part of teachers has been their demand that pupils improve regularly in the quality of their work, even though the tasks given the students vary from test to test. The demand for constant improvement in the weekly spelling test or in the monthly grade received for arithmetic implies a belief that, given time, everyone will eventually become a fast learner. With practice there should be improvement in the ability to do the same task or a similar task on the same level of difficulty. The curve of learning in spelling should represent the number of words the learner spells correctly at stated intervals of time. It cannot be used to represent the number of new words the learner can master within successive equal time intervals.

B.B.F.

LEARNINGS, SIMULTANEOUS. The concept of simultaneous learnings was developed by Kilpatrick to call attention to the fact that in any learning act the outcomes are always multiple. The girl studying history presumably learns history—"primary learning". But as she works, ideas, suggestions, questions arise out of her study—"associate learnings". These are as truly learning as the primary, for she had not previously thought these ideas, been curious about these questions. In addition learnings of a third type go on—"concomitants", the attitudes, feeling tones, judgments of value, standards, ideals.

Primary learning has until recently received chief attention from teachers. Usually it consists of facts or skills, items which can be assigned and of which mastery can be easily checked. The older generation tended to evaluate schools almost entirely in terms

LEAVE OF ABSENCE

of primary learnings, as these were the only kind recognized and sought.

Associate learning obviously cannot be assigned—the teacher cannot require the pupil to think up connections, questions, implications. But it is from these, and particularly from the disposition to think them up, that richness of knowledge and understanding come. Information is highly essential, but disposition to play with it, look beyond, integrate it with what is already known, see meanings and implications—this is what transforms mere knowledge of facts into fruitful instruments, into meaningful and illuminating insight. Though associate learning cannot be assigned, the teacher can help to stimulate it. He can, by cultivating good learning conditions, by paying attention to the setting in which facts are learned, induce in the pupil a “lowered threshold” for the arising of ideas. He can, moreover, as facts or information are sought, put stress on meaning connections, questioning, applications; he can lead pupils to see that facts are tools.

The *concomitants* or *attitude learnings* are counted by many to be the most significant of all because of their influence on subsequent behavior. Whether the child will put forth effort along any certain line and whether he will use what he learns—this depends chiefly on how he likes what he learns, how significant it seems as he sizes up the situation. If he dislikes it, if it seems unimportant for any purposes he values, then he will abandon his efforts as soon as pressure is removed and he will make slight use of the learnings. Moreover, mental hygienists, and indeed all who are sensitive to personality formation, are especially concerned with concomitants because of their meaning for wholesome emotional adjustment. The likes and dislikes formed on one occasion become, if reinforced in successive situations, one's tastes and aversions. Resentments felt and continued produce sullenness. Cumulative feelings of failure grow into a sense of inferiority or frustration. Outlook on life and behavior patterns are determined in large part by these developing attitudes. In the last analysis it is one's emotional adjustment—determined by attitudes, feeling tones, judgments built in successive situations—which sets the pattern for behavior of all kinds. M.Y.O.

LEAVE OF ABSENCE. In order that teachers may have an opportunity to improve themselves in service, many school boards grant teachers leave to be absent without affecting the teacher's tenure or contract. Usually, the teacher receives no salary while on leave of absence. Many school systems, however, pay a part of the salary, and some of them pay the full salary if the leave of absence is for approved study, rest, travel, or other purposes calculated to improve the teacher professionally. (See **SABBATICAL LEAVE.**) On the assumption that the successful completion of suitable courses of study at a college or university increases teaching efficiency, the amount of financial reward is sometimes determined by the number of credits earned.¹ (See **TEACHERS' BONUS.**)

The smaller city and rural schools, except in a few progressive systems, seldom grant leaves of absence. The larger systems, however, almost invariably provide for such leaves.³

A few schools have provisions whereby a teacher may have a leave of absence to teach in another school system for a semester or two in exchange for a teacher from that system.

Teachers are frequently granted short leaves of absence, up to approximately thirty days for personal illness with full pay. Government employees, however, as well as many of those in private concerns, enjoy greater security against loss of pay when absent because of personal illness than do teachers.² (See **SICK LEAVE.**)

In many schools where much pride is taken in the way leaves of absences are administered, granting a leave of absence amounts to the assurance that the absentee will receive his job or another one equally as good in the system when he returns. In war time many such leaves are given to those who leave their teaching posts to enter the armed services. These people are assured of re-employment when they return. D.H.C. and A.R.A.

LECTURE-DEMONSTRATION METHOD — LECTURE

LECTURE-DEMONSTRATION METHOD. The combination of lecture and demonstration is a direct teaching method, employed to set forth the relationships of facts for the learner. Its specific purpose is to show concretely the relationships as they occur—for example, the steps of a process or a procedure, the structure of an object or machine, or the nature or properties of matter. The lecture-demonstration differs from the illustrated lecture in that the latter focuses attention on the screen and shows the relationships by means of pictures, slides, moving pictures, or specimens, while the lecture-demonstration focuses attention on the lecturer, who shows the relationships through the use or manipulation of physical materials, machines, or appliances.

The lecture-demonstration is used extensively in such subjects as general science, biology, physics, and chemistry (See SCIENCE, TEACHING OF). In industrial arts and commercial subjects it is a valuable method by which may be taught the steps of processes or the manner of using appliances or machines. In many schools the lecture-demonstration has replaced much of the individual laboratory work (*q.v.*), since by the lecture-demonstration method pupils may observe the relationships when they are being studied in class. However, this method should not be used to the exclusion of individual work, since pupils should acquire the ability to use and manipulate apparatus, or to prepare and use certain materials. Each method fulfills special functions not supplied by the other.

Since the instructor can focus attention upon the important relationships, the chief value of the lecture-demonstration method lies in its economy of time. For this reason a good lecture-demonstration may be more valuable to the student than is his own first-hand experience, because the demonstrator's experience enables him to show the exact relationship to be studied and to help the student ignore unimportant details. Another

advantage in the method is that the money which might otherwise be spent for duplicate individual laboratory equipment may be used in buying a greater variety of apparatus for demonstration purposes.

The effective use of the lecture-demonstration depends upon the following steps: (1) preparation of the learner, in which the instructor leads up to the problem and stimulates a desire to learn, (2) lecture and demonstration, in which the instructor sets forth the important relationships, demonstrates the process, and then stimulates and guides critical analysis by helping pupils to compare, contrast, and evaluate, and (3) evaluation of learning, in which pupils are tested or are given the opportunity to make practical applications in order to reveal how successful the learning has been or to indicate points where reteaching is advisable. If the teacher fails to set forth the problem clearly in his lecture or fails to carry the pupil through the assimilative step, then the teaching has failed. Lecturing alone will seldom suffice; there must be an appeal to curiosity, the use of challenging questions, and careful directions for observation during the demonstration. The voice, manner, and personal bearing of the instructor play an important role in influencing the success of the method. (See LECTURE METHOD.) T.M.R.

LECTURE METHOD. The lecture method as a teaching procedure consists of an oral exposition by the teacher, usually at some length, of facts, principles, or other relationships.

The steady stream of objections to the widespread use of the lecture method arises from many sources. The psychologist, seeing learning as an active process, opposes this method because it often makes so little provision for pupil-activity (*q.v.*). The educational philosopher, emphasizing the significance of the student rather than that of subject matter, regards as outdated a method of instruction that consists so frequently of the teacher's presenting a large mass of teacher-organized and teacher-interpreted factual material for the student to accept and to memorize. The teacher finds fault with any instructional procedure where he carries so much of the burden that he has no immediate means of determining how much his students

LEGAL EDUCATION

are learning. There is always the danger that the lecturer has covered the subject to the satisfaction of no one but himself. Students, too, object, largely because so many teachers are poor lecturers, uninspired and uninspiring. Students find that they lose much of the value of the lecture when they fail to understand certain points, and there is no chance for discussion at the time when it is important to clarify doubtful points. The lecture method places at a serious disadvantage those students who have not learned how to take notes.

The lecture method has survived for centuries for many reasons, and even today, despite the many objections that have been raised to its use, it is still the basic method of teaching at many professional schools and colleges and is found occasionally in high schools. Some of the popularity of the lecture method stems from the fact that it is apparently so easy to employ. The university administrator finds it a convenient way of reducing the cost of instruction by having large lecture classes rather than small discussion groups, and the professor sees the lecture as a relatively simple procedure for presenting a large mass of factual material to students.

Many of the criticisms that have been raised are charges against bad lectures and inadequate lecturers rather than against the lecture method itself. To be sure, many classroom lectures are a wasteful use of student time because the content of the lecture is available, or can readily be made available, in printed or mimeographed form which can be read by students in a small fraction of the time it takes to present it orally. Yet, a skillful lecturer can make a complex concept or an involved procedure much clearer to students than a book can, for the observant lecturer knows when an additional illustration is helpful and he employs demonstrations and uses other audio-visual aids as the need arises. Listening to a good lecture need not be a passive process. If the students have been prepared adequately for the lecture by reading assignments and by preliminary discussion of key questions, there may be a great deal of mental activity during the lecture, especially when it is organized in terms of a series of challenging questions. The tendency today is to modify the lecture procedure so that it allows for questions by the students

on points that are not clear and for student-teacher discussion when necessary.

While a lecture may be a useful procedure for dealing with mature students, most teachers see little place for it in secondary schools and defend its use in colleges and higher institutions only when it is regarded as one of many teaching procedures to be used as the needs of the student, the subject matter, and the teacher dictate, and not as the basic method of teaching.

A distinction should be made between the use of the lecture method and the many situations in which the teacher has occasion to tell the pupils many facts or to present different points of view. Oral presentation is an important part of the teacher's work, but to characterize it as a lecture procedure belittles the significance and dignity of the lecture and is apt to rob the telling of its most vital element—the informal personal touch. (See LECTURE-DEMONSTRATION METHOD.)

LEGAL EDUCATION. Law is a public profession and carries public responsibilities. A large percentage of our public officials are lawyers, and most of our legislation is in the hands of lawyers. The interest which the State has shown in legal education from the earliest days of American history is justified by the predominant rôle lawyers play in the administration of justice and in our political life.

Public conceptions of the law and of the rôle of lawyers in society have exerted great influence on legal education. Owing, in part, to the prejudice of the original New England colonists against the English common law and its lawyers, there was no conception of the necessity for a rigorous university training in the law. Legal education in the United States followed a different course from that found either in England or on the Continent, and the English difference between the barrister and the solicitor gave way here to the development of a general law practitioner, the "attorney and counsellor-at-law."

Legal Instruction. By and large, there

are two types of legal training, one exemplified by English practice, where legal training is almost entirely in the hands of practicing lawyers and judges, in the Inns of Court; and the other the Continental method of using law faculties connected with established universities. The United States has departed from the English method but has not quite approached the Continental scheme. Since 1910 there has been a shift in American legal education from legal training in the law office to legal education in the law school. The earliest American lawyers were trained in the offices of practicing attorneys, either through lectures by successful attorneys, or by "reading" (generally of Blackstone's *Commentaries*). This method of private and practically unguided reading, coupled with practical experience as a clerk to an attorney, was the prevailing method of legal education until very recently, when the university law school came into its own as the predominant form of legal education. Today there are slightly less than 200 American law schools, and only a few states lack one.

Educational Requirements. Before the Civil War, educational requirements and "bar examinations" for admission to legal practice were not common. But after the Civil War, newer tendencies exhibited themselves, such as entrance requirements, better instructional techniques and courses, and written examinations. The last period of development, since approximately 1890, has encompassed insistence upon pre-law training and the raising of standards both for the student body and the law schools.

Pedagogical Methods. Originally, lectures and text readings constituted the basic methods of teaching in law schools. With Prof. C. C. Langdell of Harvard Law School, there developed in 1870 an entirely new and indigenous technique of law pedagogy, the case method, which since has been universally adopted in the United States. The theory of the case method operates through the collation of selected cases in terms of some significant categories, arranged historically and systematically. As developed by Langdell's student, Prof. Ames, the method required free discussion among members of the class, and between class members and the teacher. The latest pedagogical developments in legal education have grown out of disagreement with

the original assumption of the case method that all the law worth knowing was available in the "law books." Modern law casebooks, still the basic instrument of law school teachers, now include as much as fifty per cent of other than case material, such as statutes; sociological, historical, and economic data; administrative opinions and rulings; and textual notes and comments.

Improvement of Legal Education. From a comparatively early date organized attempts were made to improve the quality of legal education. In 1893 the American Bar Association set up a section on Legal Education, and in 1900 there was formed the Association of American Law Schools which has exercised a great moral influence on the course of law teaching. In 1921 the American Bar Association set up a system of "approved law schools" and of pre-legal educational requirements. Generally, these standards prescribe 2 years of pre-legal training, 3 years of full-time law study or a longer period of part-time study, an adequate law library, at least three full-time teachers, a non-commercially operated school, and the passing of a bar examination, in addition to law school graduation, for admission to the practice of law. The American Bar Association has constantly sought to modify statutes and judicial rules governing the preparation and admission of lawyers so as to approximate these standards, which have had great influence. In 1931 there was organized the National Conference of Bar Examiners.

Present Problems. Among the present-day difficulties in legal education is the lack of real professional uniformity among law schools as to courses, requirements, and methods. Some schools operate in terms of a curriculum designed to meet professional and social objectives; others, however, seek only to meet the minimum requirements of state bar examinations. Another frequent charge is the lack of a "practical" approach, that law schools are antiquated and fail to provide adequate training in statutory construction, bill-drafting, and legislation; in criminal law, procedural law, or the law of the local state. Certain devices have been designed to meet these objections; moot-courts where law students may approximate real court practice in preparing and arguing cases, legal-aid clinics where they may participate in actual profes-

sional problems in the field, and the organization of institutes for the advanced and practical legal training of practicing lawyers. These institutes have been variously sponsored by schools, alumni groups, or bar associations, and generally operate either through providing single lectures by recognized experts or by means of classes resembling university courses. The most recent complaint against modern legal education is that it is too "legalistic" and fails to adjust its curriculum to the rapidly changing social scene into which lawyers are graduated. Some attempts to meet this objection have been made on the undergraduate law level by the new type of case-book already described; on the graduate level, where instruction is designed principally for the training of teachers and research students, the newer methods approximate the French model of teaching economics and public affairs as well as "law." Other recent tendencies are the recognition that pre-law training should be non-vocational, and should be increased in amount and quality; and the growing severity of bar-examinations, whereby less than fifty per cent of the applicants on a national level are passed.

The Law School. Certain other less obvious aspects of legal education deserve mention. The modern law school revolves about its library, with thousands of volumes of law, government, history, sociology, economics, engineering, medicine, and psychology; the library plays an important role in the education of modern lawyers. Another important aspect is the "Law Review", a professional journal issued by many law schools, generally under the editorship of a board of students chosen for outstanding ability. The Review normally comprises two parts, articles by law teachers, judges and practicing attorneys; and a section prepared by the student board embracing current judicial decisions, statutory developments, and critical analyses of major legal problems. The Review serves a two-fold purpose, the training on a high level of a selected group of superior students, and the current education of its reading public—the bench and bar of the country.

LEGISLATION—See EDUCATIONAL LAW AND LEGISLATION.

LEGISLATIVE CONTROL OF CURRICULUM. Since education is a state function, the power of the state to establish educational policies is, apart from constitutional limitations, for all practical purposes plenary and unlimited (See EDUCATIONAL LAW AND LEGISLATION). This general power applies with equal force to control of policy inherent in establishing the school's curriculum. However, this authority of the state to determine the content of instruction is only one aspect of the problem; there is also the right of parents (*q.v.*) and the right of the teacher (See TEACHER'S LEGAL STATUS).

There is a wide variety of legislative and administrative practices, and a great disparity in emphasis on curriculum requirements exists among the various states. In general, three methods of control are available. One is through the legislative delegation of power to state-wide school authorities to control state courses of study and to determine the subjects and units of study which will be required for graduation from approved and accredited schools.

The second method involves direct statutory prescriptions by the Legislature. Dramatic instances of this type of control are the Tennessee evolution trial, where a teacher was convicted for violation of a state statute barring the teaching of evolution, the court upholding the constitutionality of the statute [*Scopes v. State*, 152 Tenn. 424, 289 S.W. 363, (1925)]; and statutory prescriptions for military training, which have been upheld as valid [*Hamilton v. Regents of University of California*, 293 U.S. 245 (1934)].

There are many hundreds such statutory requirements in the country, generally more common on the elementary than on the secondary level. An early study by Flanders in 1923 disclosed 926 prescriptions covering a wide variety of categories: nationalism (flag displays, government, constitution and history holidays); health and prohibition (accident prevention, stimulants, physiology and hygiene); practical and cultural subjects (agriculture, music, industrial arts, cotton-grad-

ing); humaneness to animals and birds; "fundamental" subjects (arithmetic, English, geography, penmanship, reading, spelling); and religious and ethical subjects (Bible-reading, manners and morals). At least three-quarters of the states have prescriptions for the teaching of the "fundamental subjects", and all 48 states require instruction in the nature of alcoholic drinks. Some statutes even prescribe the method of pedagogy (by "oral and black-board instruction"), and others go so far as to set the precise time of day when the prescribed instruction is to be given.

Legislative prescriptions of curriculum content frequently result from the actions of pressure groups, as witness the universal requirement of teaching the effect of alcohol, and the number of "monkey-instruction" bills. The evil that results from such legislative reflection of lobby pressures rather than of the considered judgment of educational experts can be seen in the California history of 70 years up to 1921, where 53 subjects were written into the elementary curriculum, 22 of which were later dropped.

A third method of controlling curriculum content is directly through the purse-strings, particularly by means of the device of state-aid or special financial aid to encourage authorized, but not required, subject matter. Sometimes the Legislature merely authorizes the instruction of certain subjects; other times it encourages development therein by paying part or all of the attendant costs. (See CURRICULUM.) H.N.R.

LIABILITY. Liability is a legal determination that one person must reimburse another for damages caused by the first person's improper activities. In terms of schools, generally there are two forms of liability, (1) contractual, and (2) tortious.

Contractual liability arises when a properly constituted judicial tribunal rules that there has been a breach of a contract, as a result of which the party at fault must make amends to the injured party. No contractual liability can take place unless there is a valid contract. There are two aspects of school contracts, one deriving from the general law of contracts, and the other from the peculiar nature of a school board as a contracting party. Certain fundamental rules of contract law condition all school contracts. A contract is an agreement between at least two people, enforceable by the law, wherein at least one party promises to do or to refrain from doing certain things and the other party in turn conveys something of value in exchange for the promise. There must be a "meeting of minds" as it is called, on the subject matter of the contractual obligation; by and large this can be achieved when the proposition or offer of one party is accepted by the other. And the promise of the one side must be met by what the law calls a valuable "consideration" or exchange by the other. Purely one-sided commitments do not achieve the status of legally enforceable contractual obligations. Furthermore, no legally enforceable contract may contemplate an unlawful object. This latter general principle of contract law ultimately may prove of great protective force for teachers whose school boards seek to evade the policy of tenure laws by requiring teachers to sign undated resignations at the time of accepting contracts which might mature into tenure status.

In addition to the general principles of contract law which govern school contracts, other restrictions grow out of the peculiar nature of school boards. A board of education is a creature of statute (see EDUCATIONAL CORPORATION) and consequently cannot claim any inherent rights to enter into contracts. The board's rights to contract must be traced to statute either directly or im-

LIABILITY

pliedly. Not only must the object or content of the contract be justified by statutory authorization, but the form of contracting, the method of award, and other procedural aspects of the contract must find their authority in the statutes. Consequently, it is a universal rule of law that school contracts entered into in excess of school board authority are unenforceable. Contracts beyond the scope of authority are known as *ultra vires*, and grant the other party no legal rights under the contract. Where the contract is not *ultra vires* but merely void for failure to obey statutory standards, in some unusual instances a contractor who has furnished goods or services the benefit of which has been retained by the school board may recover the reasonable value of such goods or services. All who deal with school corporations are presumed to act with knowledge of the school board's limited powers. All contracts by school authorities have read into them the statutory and constitutional limitations on such bodies. School board bylaws are frequently implied parts of school contracts. Besides the negative limitation of failure to find statutory authorization to engage in certain types of contract, school boards are subject to the positive limitation of compliance with any specific statutory procedures or requirements adopted by the Legislature. This affirmative type of limitation may include, to list a few examples, a requirement of a written contract, a requirement for competitive bidding upon public advertisement and letting, a direction that all school contracts of a specified type must require a majority vote of the entire board membership and not merely a majority of a quorum at any meeting, or a mandate that certain types of contracts may be awarded only at specially called board meetings. Unless otherwise specifically provided by law, contracts may be made only by the school board acting *as a board*, and not by a building committee, the board president, or the superintendent.

Where a school board contract has been entered into lawfully, the school board is obligated to the performance of all of its contractual undertakings; for failure to perform them it may be subjected to liability, or judgments for money damages payable out of tax funds. With rare exceptions (one of which may be impossibility of performance because of governmental action), the occur-

rence of events subsequent to the making of the contract will not relieve a contracting party from the performance of his obligations under the contract.

Tortious liability. A tort is a civil wrong not involving a contract. In most school cases it involves injuries caused by negligence (*q.v.*). There are but few cases in the law where absolute liability exists, that is, where liability arises from the mere occurrence of an injury. In most instances, liability is a direct function of negligence. Where negligence exists, and no legal defenses are available (See NEGLIGENCE), there are three interests which may be held liable in a school accident: (a) *The School Board*. The almost universal rule of American law exempts a board of education or school district from any corporate liability either for its own negligence or for the negligence of any of its employees. With certain minor exceptions, this basic rule of governmental immunity of school districts is applicable in forty-five states in this country. The principal exceptions are California, which permits school boards to be liable on the same basis as private corporations; Washington, which follows the California rule except for accidents in connection with physical or manual training; and New York, which in effect holds school boards liable for all injuries except those caused through the negligence of teachers. There is a slowly growing trend toward statutes abrogating the nonliability rule, and subjecting the school board to liability for negligently caused injuries; (b) *The Employee*. Except in some instances, all teachers, principals, superintendents, maintenance, clerical, and administrative employees are always personally liable for their own negligence, subject to certain legal defenses (See NEGLIGENCE). They gain no exemption from liability for their own negligence because of the immunity of their employers; (c) *The School Trustee*. With exceptions so rare as to make the matter of little moment, no personal liability attaches to school board members in the performance of their official duties requiring the exercise of discretion and judgment.

LIBERAL ARTS COLLEGE. In recent years, the liberal arts college has been subjected to severe criticism. Its eclectic nature has been ascribed to lack of a philosophy of education, and its inclusion of vocational and technical courses has been decried both by professional schools and by the proponents of education for culture. The lengthened period of training for all professions has led to a demand for curtailment of the liberal arts college.

The college of our day is not a common school—a school for all. It is designed to help intellectually able young people find themselves and prepare themselves to live a richer and a deeper life.

And yet the college, in achieving its basic aim, has served secondary aims: It has given the bases for professional education; it has maintained a diversified curriculum to serve all legitimate interests and to contribute toward individual self-realization; it has stressed habits of work and attitudes which

make for success in adjustment to life. The leading schools of medicine, law, engineering, and business have made college graduation a requirement for admission and have asked the college to focus its effort on liberal rather than on technical studies, on a broad rather than on a specialized curriculum. The college maintains that the best preparation for making a living is to learn to live, that the vital educational question is not what one can do with the college subjects he learns but rather what they can do to him in preparing him for leadership in a democratic society. On this philosophy the liberal arts college will stand or fall.

History. The earliest colleges—Harvard, 1636; William and Mary, 1693; Yale, 1701; Princeton, 1746; King's College (later Columbia), 1754; and Dartmouth, 1769—were established to train for the ministry. Later the curricula included law, teaching, and medicine; and gradually, almost incidentally, the college purpose became associated with the other learned professions and with civil life.

Growth of Enrollment. After 1900 the college enrollment experienced a growth unprecedented in the history of education. This is summarized in the following table.

Table 1
Student Enrollment in Higher Education*

Year	Population		Student Enrollment in Higher Education	Per Cent That Student Enrollment Is of the General Population	
	(Total)	(Ages 18-21)		(Total Pop.)	(Ages 18-21)
1900	75,994,575	5,930,765	237,592	0.31	4.01
1920	105,710,620	7,343,794	597,880	0.57	8.14
1930	122,775,046	8,899,254	1,100,737	0.90	12.37
1938	130,215,000	9,679,000	1,350,905	1.04	13.96

*Biennial Survey of Education in the United States, *Statistics of Higher Education, 1937-38*, Bulletin 1940. No. 2, Ch. IV, Federal Security Agency, United States Office of Education.

From the above table, the following conclusions may be drawn:

1. In 1900 fewer than one-third of 1 per cent of the total population were enrolled in college; in 1938 more than 1 per cent were so enrolled.
2. In 1900 a little more than 4 per cent of persons 18 to 21 years of age were enrolled in college; in 1938 nearly 14 per cent of persons of these ages were so enrolled.
3. Increase in college enrollments during the

period from 1900 to 1938 was 468 per cent, while increase in the total population was only 71 per cent, and increase in population of those aged 18 to 21 years was only 63 per cent.

4. In 1900 there was one college student to every 24.9 persons aged 18 to 21 years; in 1938 the ratio was one to 7.2.

Among the causes of this growth in student enrollment should be included the imperative need for trained public personnel in a demo-

LIBERAL ARTS COLLEGE

cracy; the increasing application of the lessons of science to commerce and industry; the secularization of education; the aristocracy of learning associated with the quest for economic security; local pride and the bounty of those who accumulated large for-

tunes; the belief that democracy should assure equality of opportunity to all of proved worth.

The number of colleges in the United States and the source of their support and control are summarized in Table 2:

Table 2
Colleges in the United States, Their Number and Their Control*

Type of Institution	Publicly Supported or Controlled	Privately Supported or Controlled	Denominational Control**		Totals
			Protestant	Roman Catholic	
College or University	110	182	253	145	690
Junior College	235	90	108	33	466
Negro Institutions					
College or University	19	6	38	1	64
Junior College ...	4	2	17	0	23

*Classification and distribution follow from table entitled "Control of Higher Education," *Educational Directory, 1941-42, Part III, Colleges and Universities*, Federal Security Agency, United States Office of Education, p. 7.

**One college, in New York, under Jewish control, was not included in the government's summary.

Overlapping Other Institutions. Because the college is intermediate between the secondary school and the university, much that the college teaches is found naturally in curricula of the high school and the university. Courses of similar grade in foreign languages, introductory science, elementary mathematics, and English are found in both the college and the secondary school. Frequently, courses in the upper college classes compare favorably with similar university studies for the Master's degree. These duplications, needless and confusing though many of them are, were introduced to assure individual students the opportunity to pursue progressive studies in keeping with their abilities and changing interests.

Student Elimination from the College.

Out of every 100 students admitted to the secondary school in the United States, only 55 are graduated, only 17 enter college, and only 8 receive the college degree (J. H. McNeely, "College Student Mortality," *U. S. Office of Education Bulletin*, 11, 1937). The acuteness of the misfortune lies not in the number eliminated but rather in the significant number of students of proved ability who are denied an opportunity for higher education because of economic disability.

The most common cause of elimination is lack of ability or lack of preparation for college work. Far too many students come to

college with reading disabilities, lack of adequate study habits, disinterest in the world of books, or limited intellectual capacity. To these causes we must add changes in interests, lack of guidance in secondary schools or colleges, personal maladjustments, and ill health. These causes of academic elimination are not discrete; often two or more operate toward the same end.

Many corrective measures have been devised. A measure of student guidance is assured through cooperation between the college and the secondary school, especially where the college knows which secondary schools its students come from. Orientation programs from two days to a semester are given to freshmen. Special groups are organized of those who need guidance in the technique of study or remedial exercises in reading. Homogeneous grouping furthers adjustment. Systematic student guidance or personnel work reveals many students who are in danger of being overwhelmed owing to economic pressures or because of personal maladjustment. (See **ELIMINATION**.)

How Students Are Admitted. Admission to the college, in the main, is in terms of achievement in preparatory studies. The pattern of requirements is not too fixed, but the applicant is expected usually to have completed creditably:

LIBERAL ARTS COLLEGE

4 years of study in English.....	3 credits
2 or 3 years of study in a foreign language	2 or 3 credits
2 years of study in elementary mathematics	2 credits
1 year of study in social science...	1 credit
1 year of study in physical science..	1 credit

These make a total prescription of 9 or 10 credits. With these the pupils must offer additional credits to make a total of 15 or 16. He is free to continue the above subjects or to choose from almost any of those offered in accredited secondary schools. The number of applicants for admission determines whether a quality standard is added. Other factors that determine admission are scholastic aptitude tests, personality ratings, and geographic distribution of the applicants.

A recent study of applicants who were admitted to college solely on the recommendation of thirty selected secondary schools reveals that no set subjects need be taken to assure success in college (See EIGHT YEAR STUDY.). Good habits of work and a command of English seem to be the basic requisites. All of the thirty secondary schools taught—each in its own way—mathematics, English, foreign languages, social studies, sciences, and arts. True, in some of the schools mathematics and science were interrelated, while in others they remained separate subjects; in some schools, students were taught general language before the foreign language while in others, the students proceeded directly to foreign languages. In the last analysis, the subject matter that is foundational in prescribed college studies was the backbone of the secondary school curriculum. The question is one of method rather than of content. The most reliable single predictive agent of success in college is still the cumulative academic record in the secondary school.

Individualization of Education. With the rapid growth of college enrollments and the increasing scope of knowledge, two potential dangers appeared: (a) mass education with its neglect of the individual and (b) a widened channel of knowledge with a discernible shallowness.

In order to individualize instruction, supplementary teaching devices were adopted. Among these are the tutorial system, associated with Harvard and Princeton; seminar or workshop courses; reading periods; field work; comprehensive examinations based on

independent reading by the student; honors courses, as evolved first at Swarthmore; supervision of the elective program, which aims to give each student a proper degree of concentration in a field of knowledge as well as a proper distribution of studies.

To guard against an overwide curriculum with its accompanying shallowness, survey courses were evolved in the humanities, in the social sciences, and in the physical sciences. With these overviews of large areas of knowledge, the student is deemed reasonably well prepared for that intensive study which will satisfy his interests or lay the foundation for his later professional work.

To make its curriculum an instrument for developing a disciplined mind, the college has renewed its emphasis on method as well as on mastery of subject matter. Each of the important subjects is expected to acquaint the student with its characteristic method of thinking. The Hutchins plan as carried out at St. John's College is probably an extreme example of the revived emphasis on discipline.

Faculty and Student Participation. The general tendency in college administration is to repose in the faculties the responsibility for academic standards. The traditions of each institution determine the extent of faculty participation in administration procedures. Student self-government is encouraged so that the burden of student control falls on the students. The governing boards control fiscal policies and salaries. To the president is assigned the affirmative responsibility of maintaining and promoting the total educational program of the college. (See BLACK MOUNTAIN COLLEGE PLAN; CHICAGO PLAN; COLLEGE ENTRANCE REQUIREMENTS; COLLEGE FACULTY; COMPREHENSIVE EXAMINATIONS; MUNICIPAL COLLEGES AND UNIVERSITIES; PRECEPTORIAL METHOD; ROLLINS COLLEGE PROGRAM; STATE COLLEGES AND UNIVERSITIES; TUTORIAL INSTRUCTION.)

LIBRARIAN—See **LIBRARY PERSONNEL**.

LIBRARIES, COLLEGE. Just prior to 1931 the Carnegie Corporation of New York gave one million dollars to approximately eighty liberal arts college libraries for books and periodicals. Studies were made and recommendations presented as to suitable books for inclusion in college library collections. Higher standards for support and administration were set by regional accrediting agencies. In general, so much attention has been paid to the problems of personnel, support, and services in libraries at this level since that time that L. R. Wilson speaks of 1931 as the year of emergence of the college library.¹

Libraries in colleges serve at least three groups of people—their students, their faculties, their alumni, and occasionally the surrounding public. Students must not only be provided with reading and audio-visual materials necessary for their courses, but they must be encouraged and helped to read widely and wisely for personal growth and pleasure. Colleges provide this latter service by means of attractive non-curricular reading rooms in the library (frequently called "browsing room"), by deposits of recent and interesting books in dormitories and fraternity houses, by sponsoring book auctions, by giving awards to students for excellent personal

libraries. Some colleges, aware of the large number of their students who cannot read at college level, offer personal or class reading guidance in the selection of suitable reading material and in the understanding of what is read. The introduction of honors or reading courses in many colleges has increased both curricular and non-curricular reading.

Students in most colleges are given some instruction in the use of the library. The amount varies from a lesson or two to a course which extends over a quarter or semester. Graduate schools frequently offer courses in the technique of library research as a prerequisite to graduate study.

Faculties must have not only adequate reference materials for their students, but current literature in their fields and materials for research.

Many college libraries provide all their graduates with annotated reading lists of timely books, and, when proximity permits, with the books themselves.

The planning of college library buildings follows the current trend towards the functional. Generally speaking there is a tendency to break up one or two large reading rooms into several small ones, though even this is dependent on the number of staff members available. Some new college library buildings provide open air reading rooms; typing rooms; and rooms in which to use microfilm, phonographs, and radio. Some college libraries are now providing for the accommodation of as many as 40 per cent of their student body at one time, instead of 10 per cent which was formerly thought to be sufficient.

The administration of college libraries is usually vested in the librarian, who is directly responsible to the president of the college. There is frequently a faculty library committee whose function is usually advisory. Occasionally some members of the board of trustees of the college form an advisory library committee.²

Income for library purposes generally comes from three sources—an appropriation from the annual income of the college, student library fees, and endowments made especially for the library.

Statistics of expenditure for libraries by a group of 58 colleges of less than one thousand undergraduate students showed that in

1940-41³ the median amount per student spent for library materials and service was \$22.39. This was 4.7 per cent of the educational expenditure for the college. This was a slightly better showing than was made by a group of 53 colleges and universities which had an enrollment of more than one thousand undergraduates. Widespread investigations indicate that the library budget should be based not on student enrollment, but on a study of the actual cost of adequate library service in a particular institution. (See LIBRARIES, UNIVERSITY AND RESEARCH.) E.S.

LIBRARIES FOR THE BLIND. The adult blind of the United States are provided with books and magazines in Braille and Moontype (See TOUCH READING). and with "talking books"—records and phonographs—by the Federal government acting through the Library of Congress. A designated public library in each of twenty-seven districts serves as the local distributing agency under the supervision of the Library of Congress, and receives financial aid for the administration of this service. In addition to the \$350,000 which the government now allows annually for books for the blind, free transportation of the materials is allowed. (See BLIND, EDUCATION OF THE) E.S.

LIBRARIES, NATIONAL. The Library of Congress is one of the great national libraries, built up by the government through purchases, gifts, exchanges, and the deposit of two copies of every book copyrighted in the United States. It has numerous special collections, such as the one on music which consists of books about music and musicians, and sheet music. Its collections of maps; manuscripts; public documents, both of foreign countries and of the United States; newspapers; and Americana are especially important. One of the earliest purchases of the Library of Congress was the library of Thomas Jefferson. A recent one, in 1930, was

the Vollbehr collection of incunabula. Possibly the largest group of books on aeronautics in the world is in the Library of Congress. The total number of books and pamphlets in the Library is approximately 6,000,000. This does not include manuscripts, sheet music, maps, or charts, of which there are several millions more.

Scholars everywhere make use of the collection by consulting materials at the Library or from a distance, through inter-library loans of books, films, or photostatic copies of needed material. The Library of Congress also aids research workers by issuing bibliographies of current material in special fields, and indexes to publications of various federal agencies.

The classification scheme for which it is responsible; its system of printing and distributing catalog cards; its union catalog which contains the cards for books in about 700 great libraries besides its own, including the highly specialized government libraries in Washington make it an invaluable technical and professional aid to other libraries as well as to scholars.

There are more than 150 government libraries in Washington. The Department of Agriculture, the Smithsonian Institute, the U. S. Geological Survey, the Office of Education (*q.v.*) are typical of the fields in which these libraries specialize.

The Office of Education Library contains approximately 275,000 volumes. The collection also includes courses of study; theses on education; and all possible resources to aid the staff of specialists in the Office of Education and teachers and school administrators throughout the country, by means of inter-library loans, and reference and bibliography service.

In 1936 the Congress appropriated funds for the establishment of a Library Service Division in the Office of Education for the purpose of forwarding library development in the United States. This was the first official evidence of leadership on the part of the Federal government in the promotion of nationwide library service. The Division has been assigned several functions, the first and chief of which is research. E.S.

LIBRARIES, PUBLIC. Public libraries may be defined as agencies which supply free

LIBRARIES, PUBLIC

library service to persons within their communities.

The extent to which people are receiving this service is steadily increasing, as is shown by the fact that in 1926 forty-three per cent of the population of the United States was without access to libraries, and in 1935 only thirty-seven per cent were in this group.¹ Later studies indicate steady improvement in many regions, but there are still more than 35,000,000 people who live in areas, chiefly rural, not supplied with reading materials by free public libraries. Since evidence gathered from many sources indicates that public libraries are the chief source of reading for the largest part of the American public, except for newspapers, these figures mean that just so many people do not read.

Local public libraries in cities and towns offer varied services to their patrons, depending on their size, location, and resources. Besides supplying books, magazines, and pamphlets many of them lend lantern slides; pictures, some with frames ready to hang on walls; phonograph records and sheet music; books in Braille and "Talking Books" for the blind. (See LIBRARIES FOR THE BLIND.)

Branch libraries exist in large numbers, and their work is supplemented by "stations"—collections of books deposited by the public library in schools, factories, and other places. Outlying districts not served by a nearby branch are reached by bookmobiles, or book trailers, which stop at scheduled times and places.

Business and technical departments or branches offer special materials and services to patrons who need them. Patients in hospitals are often served by large city libraries. Some libraries maintain rooms for the professional reading of teachers. A few have rooms devoted to books, magazines, pamphlets, and bulletins for parent education, in response to a constantly increasing demand. Clubs are often served by a staff member who does little else. In some large cities, libraries provide special service for public and parochial schools and colleges in the form of special loans for a stated period.

Work with the foreign-born in many towns and cities has been an important part of library service, requiring a skilfully selected staff as well as a carefully chosen collection of books. Since 1933 much of this work has been

with refugees, many of whom are well educated and need a different type of service from most immigrants who formerly made up the group of foreign-born.

Readers' Advisory Service, as a special service, is a recent development in libraries. It is now handled by one or more specially equipped members of the public library staff. Any reader who wishes may have advice and reading lists on any subject. People who wish to continue their education from any level, or who wish re-education for another kind of work, are given reading courses with as many conferences as they wish. Readers' advisers sponsor forums, classes, and lecture courses.

Public libraries have long given service of the highest quality to children; and more recently many of them are giving special attention to adolescents and young adults, by means of reading rooms, suitable collections, and a staff whose interests and training are in this field.

The above list of activities can be lengthened, but it suggests what adequate library service can become, with sufficient resources by way of staff and materials.

Rural areas, when they are supplied with library service at all, are reached in several ways. Many state libraries send travelling collections of books to towns, schools, or individuals having limited service or none. Forty-six states have library extension agencies whose chief function is to promote, organize, and supervise state-wide library service.¹

The county library, supported by county funds, functions well in some states, for example in California. The county plan pools existing library resources, permits trained service, and provides for wide distribution of materials in various ways.

Many counties, however, have populations and taxable properties which are inadequate to support libraries within themselves. Regional libraries, which combine the resources of several counties, are being encouraged and tried.

Support for public libraries differs from support for education in general in that it is not legally mandatory in most states, but merely permissive. This means that there are at present only a few states which give financial support to public libraries—Michigan, New York, several New England states, and a

few others.² The local unit—city, township, county—is financially responsible in most cases for its own library service.

The per capita amount spent by the total population for public libraries in 1934 varied from \$1.08 in Massachusetts to \$.02 in Mississippi and Arkansas.² The per capita amount in terms of population served by libraries varied slightly less—from \$1.08 in Massachusetts to \$.11 in Arkansas and \$.08 in Mississippi. The average per capita expenditure was \$.37. State and national library association work steadily for equalization of library opportunities, which cannot be attained without state or federal aid to local units.

The administration of public libraries outside of cities follows the same pattern of administration—a county or regional board chosen by the unit which supports the library. The state library agency, whether it is a commission, a library department, or a state library whose staff is responsible for library extension, is advisory in its relationship to public libraries, rather than administrative.

The administration of public libraries in most cities of 30,000 or above is in the hands of library boards, members of which are sometimes elected, sometimes appointed. A few cities have libraries administered by boards of education; and a few city libraries are controlled directly by the city council, commission, or city manager.³ (See LIBRARY PERSONNEL.) E.S

LIBRARIES, SCHOOL. The function of a school library is to contribute to the fulfillment of the educational aim of the school. It does this by selecting, collecting, organizing, and distributing materials of all kinds for use in class work; by individual and group guidance of pupils in reading for school purposes or personal recreation; by furnishing the facilities for teaching children how to find materials they need and how to evaluate and use these materials; by helping

children to become intelligent users and supporters of public libraries.

School libraries are organized in elementary, junior, and senior high schools, but those at the elementary level are generally the least developed in school systems. They vary in type from collections of books in classrooms, haphazardly selected and arranged, to well-equipped central library rooms which help in every possible way to carry out the program of the school.

The need for libraries in junior and senior high schools and the importance of their services are much more generally recognized. They exist in far greater number, are subject to more supervision by state and regional authorities, and are generally under the direction of better trained personnel.

Changes in educational philosophy have had considerable effect on school libraries, but the planning of the physical plant has not generally kept pace even with obvious additional services to be rendered. Few school library suites have sound-proof rooms for listening to music or other recorded material. In relatively few schools is there a room connecting with the library which can be used as a laboratory where a class can have immediate access to all library materials while a unit is under way. Few schools have small, attractive rooms for recreational reading, such as the "browsing rooms" in many college libraries. Space and flexibility should be the chief aims of school library planning.

In many schools the library is not allowed to make its greatest possible contribution to the students' educational development. Some schools still look upon the school library as only a convenient place for storing books and have failed to take advantage of the many ways in which a competent librarian can help students to use the library facilities with satisfaction and enjoyment. The full educational use of the school library is not achieved through short series of special lessons on the use of the card catalogue and references books. For the school library to be of greatest value it must be seen not as a separate room, but as a part of the school³; and the librarian must have the responsibilities and the opportunities of a member of the teaching staff.

The problem of the most satisfactory and economical administration, control, and sup-

port of the local school library has not as yet been solved. Three types exist—libraries supported and controlled entirely by the school district, those over which both the public library board and the school board exercise control because of joint support, and those which are public library branches in school buildings. Of 53 cities of 30,000 inhabitants or more, 39 have school libraries which are administered by the school board, and 14 which have a cooperative plan.¹ There are numerous valid arguments for each form of administration.

School libraries in secondary schools have grown up most often as separate units, and in many school systems continue to function in that way. Centralization of all school libraries within a school system, whether administered by the public library or the school board, is, however, economical and sound. A division or department of school libraries, administered by a director or supervisor, exists in 14 cities of 50,000 or over.¹

In 13 states there are state school library supervisors,¹ either connected with the state department of education, or on the staff of the state library. These positions carry varying responsibilities and duties which are promotional and advisory, not administrative.

Schools in rural areas have book service of one of three kinds, if they have any at all. This service is given either by county public libraries (See LIBRARIES, PUBLIC) or by travelling book collections sent from the state library agency; or by libraries established from county school funds in the headquarters of the county superintendents of schools, and administered by them, sometimes with aid of trained personnel, sometimes without.

State aid for school libraries is legally provided for in 17 states.¹ In 11 other states the legislation is permissive. The variation in amount is so great that it is obviously another symptom of the great need for equalizing educational opportunities for all children.

When school libraries are supported and administered by the school district alone, there are still numerous opportunities for cooperation with public libraries.² Some examples of cooperation are: the lending of large collections of books by the public library to classrooms for long periods of time; reserve shelves in the public library for use

in various school units; notice to the public library of future demands for books by the school librarian or teachers; cooperation in planning units by public librarian and school group, representation of the public library on school curriculum committees; cooperative bibliography making; visits of elementary or junior high school classes to the public library. (See also LIBRARIES, PUBLIC. For Personnel, see LIBRARY PERSONNEL.) E.S.

LIBRARIES, UNIVERSITY AND RESEARCH. Opportunities for research are found in university libraries, as well as in many public and private collections throughout the country. Harvard University has probably the largest number of special collections, ranging in subject through classical literature; individual English, French, and German authors; drama; history of various countries and periods; fine arts; city planning; philosophy and religion; the social sciences and most branches of science. Other universities, such as Yale, Cornell, Columbia, Michigan, to mention only a few, have special collections for ten or more subjects.¹

Many college libraries have specialized in subjects of interest and importance, for example Amherst, which has a Wordsworth collection; and Colby, which has unusual material for research on Thomas Hardy and E. A. Robinson.

A few large public libraries, notably that of New York City, have valuable research collections. The basis of this library was the combination of three private libraries which had already acquired many rare and valuable items. It was also the recipient of large endowments at the time of its foundation.

There are special collections for research in the libraries of certain state historical societies, the American Antiquarian Society, and the Hispanic Society. The largest art museums have excellent collections in their

field. Numerous public utilities have built up extensive research libraries.

Private libraries have been built up, which contain highly specialized materials invaluable for research. The Henry E. Huntington Library at San Marino, California, specializes in materials on early English literature, Shakespeare, seventeenth and eighteenth century manuscripts, English drama, and Americana. The John Crerar Library in Chicago, established in 1894, contains materials on the theory and practical application of physics, chemistry, botany, ornithology, and other fields of science. It has a large collection of materials on transportation. Newberry Library, also in Chicago, contains more than half a million volumes chiefly in the fields of history, the classics, and literature of various countries. The Henry C. Folger Library in Washington, D. C. contains the finest collection of Shakespeare material in the United States. There are more than 40 first folios in the 20,000 volumes. It has also specialized in materials on Dryden and early English printing. John Pierpont Morgan collected English and American manuscripts, early printed books, and various other rare items of English and French medieval literature, to the extent of 25,000 volumes, valued at \$7,500,000. In 1923 this library was given to the city of New York by the son of its founder as an institution for research. (See LIBRARIES, COLLEGE; LIBRARIES, NATIONAL.) E.S.

LIBRARY PERSONNEL. At the present time there are thirty library schools in the United States and two in Canada which have been accredited for training librarians by the American Library Association Board of Education for Librarianship.¹ Requirements for entrance and for obtaining degrees from these institutions vary. There is also some specialization in the kind of librarianship for which they prepare. Persons who have fulfilled the requirements of one of these training agencies are classified as "professional."

For the purposes of uniform statistics, the American Library Association has grouped and defined library personnel as follows: administrative office assistant, professional assistant, sub-professional assistant, clerical assistant, and others.²

Administrative office assistant applies to such positions as secretary to the librarian, or business manager. These persons need have no training in librarianship.

A professional assistant must have at least a bachelor's degree, and one year of professional library training, which may be included in the four years required for the bachelor's degree; or, education and experience of a kind which is considered by the librarian in charge equal to four years of college and five years of professional experience.

A subprofessional assistant should have some elementary training in library work.

A clerical assistant rating requires graduation from high school but no training in library work.

"Others" are those who do minor clerical or manual library work—pages, for example; but book menders and the custodial staff are not counted here.

There is a definite tendency towards certification of librarians in publicly supported libraries—municipal, county, and school. A recent survey shows some interesting trends.³ Eighteen states have some kind of legal certification for some type of public librarian. A few of them indicate requirements for county librarians only—a provision evidently written into the law establishing or permitting county libraries, which are a fairly recent development. Most of the provisions for certification were made since 1930.

In twelve states there is *voluntary* certification of librarians in public libraries. In most cases the certifying agency is the state library association, which has made detailed and specific requirements. This awareness on the part of the profession itself indicates that once the experimental stage is past, there should be a demand for legal certification.

More than half the states now require certificates for school and teacher librarians. Some of the statements about certification in-

LICENSING OF TEACHERS —LIGHTING, SCHOOL

clude regulations about the amount of time per pupil enrollment a librarian or teacher librarian shall be required to serve in the library. Some states make the same requirements for librarians as they do for teachers, plus approximately a year of library training, in a course of four years work toward a bachelor's degree.

School librarians are certified in two ways, either by legislation or in accordance with standards set up by the same state committee, or board, or other officials, who certify teachers according to approved standards. The trend is towards the latter procedure.⁴

Of school librarians in cities where school libraries are administered by the boards of education, ninety-eight per cent have the status of other faculty members,⁴ with eighty-eight per cent of them on the same salary schedule. In cities where school libraries are under the cooperative administration of the Board of Education and the Library Board, only twenty-five per cent of the school librarians have faculty status.

LIFE GUIDANCE—See GUIDANCE.

LIGHTING, SCHOOL. Standards for schoolroom illumination are being revised continually with increased recognition of the detrimental effects of poor vision and ocular fatigue on the health of the child and on school progress. The American Standards Association in 1938 revised its standards adopted in 1932 as follows:

	1932 Minimum Standard (Intensity in foot candles)	1938 Proposed Standard
Classrooms, study halls, lecture rooms, and libraries	5	15
Offices	5	15
Sewing rooms, drafting rooms, art rooms, and rooms where fine detail work is to be done	8	25
Shops and laboratories	5	15
Gymnasiums	3	15
Auditoriums, cafeterias, and other rooms in which people congregate for an extended period, but not for study	2	6
Locker rooms, stairs, corridors, and toilets	1	4
Sight-saving rooms	30

Even the revised standards are challenged by many authorities as being much too low. It is an accepted principle that illumination should be sufficient for the most eye-straining task in the classroom.

Windows. A majority of classrooms receive their natural lighting through windows. The minimum natural lighting requirement is usually one square foot of window space to each five square feet of floor space. This proportion should be increased where exterior obstructions exist. Since one square foot of glass area at the top of the window is several times as effective as one square foot at the bottom, modern school buildings have the glass line of their windows as near the ceiling as possible. A commonly accepted rule is that the top of the window should be square and should extend to within six inches of the ceiling, and that the minimum distance from the top of the window to the floor should be equal to half the width of the room.

Color of Walls and Ceilings. The reflection and diffusion of light in the classroom also are important factors in classroom illumination. Ceilings and walls should be finished with colors of high light-reflecting values. Colors frequently recommended for walls are light buff or light green; ceilings should be white or near-white. All colors should be of dull finish to eliminate glare. The ceilings should reflect from 65 to 80 per cent of the light and the walls from 50 to 60 per cent.

Window shades should be translucent, preferably tan in color, and should be adjustable to admit the light from the upper part of the window.

Artificial lighting. Artificial lighting equipment is classified according to type of installation: direct, semi-direct, semi-indirect, and indirect. Direct lighting is provided by suspended lamp bulbs without reflectors; this type of fixture gives high concentration of light but poor diffusion and is generally considered unsatisfactory. Semi-direct lighting is usually provided by frosted glass globes, permitting a large percentage of the light to shine directly on the working plane and a small percentage to reflect from the ceiling. Semi-indirect lighting, usually obtained by use of opaque plastic or glass reflectors, throws the greater percentage of light on the ceiling, from which it is reflected to the working plane. Indirect lamps reflect light from the source to the ceiling, permitting no direct rays to fall on the working plane. Semi-indirect and indirect lamps are preferable because they considerably reduce glare, although they require greater intensity to give an equal foot candle of intensity on the working plane.

Fluorescent lighting gives promise of greatly improving lighting intensities without increasing wattage. L.E.M. and M.F.S.

LOAN FUNDS. Moneys reserved or used for lending constitute loan funds. Specific examples are loan funds for students and for teachers.

Institutions, agencies, organizations, and individuals set aside loan funds available with or without interest to students, the principal usually being paid back in installments. In contrast to scholarships and gifts, the principal at least must be returned. In 1942, to promote the interests of national defense, the federal government established a loan fund available at a set rate of interest to students in such special fields of preparation as chemistry and engineering.

Less common are loan funds for teachers. These funds may be used for such purposes as travel, additional schooling, living expenses, and emergency needs.

Where loan funds for teachers are not available, many teachers have been forced to borrow money from other sources, often at unduly high interest rates. The teachers' credit union has been proposed as a means of helping teachers to solve their financial problems.

A credit union for teachers is an independent and voluntary organization of teachers incorporated for the two-fold purpose of 1) providing loans for provident and productive purposes and (2) promoting thrift among its members.

The credit union movement dates back to the 1850's in Europe. The movement in the United States was quickened through the efforts of Edward Filene, a Boston merchant and philanthropist, who spent considerable money in an educational program which resulted in favorable legislation for cooperative credit unions.

There are more than 9,000 credit unions in the United States and a national organization known as the Credit Union National Association. Many of these local unions are for teachers and other employees of boards of education.

A group may organize under state or federal laws. In Illinois, credit unions formed under the state law are supervised by the auditor of public accounts, and those formed

LOCAL BOARD OF EDUCATION — LOYALTY OATHS

under federal statutes are supervised by the Farm Credit Administration.

The Governing body is usually a board of directors who appoint a treasurer and managing officer. Careful supervision is exercised through various local committees. The directors and officers are elected at the annual meeting, at which all persons holding shares of stock have voting privileges. At the annual meeting the credit committee is usually elected for the purpose of passing on all applications for loans. Under the federal law, loans up to \$100 may be made without further security than a promissory note signed by the borrower. C.A.D.Y.

LOYALTY OATHS. Legislatures or State Boards of Education in at least 24 states now require a loyalty oath of teachers. Although one such loyalty oath requirement existed as early as 1862, in Kentucky, the great impetus to this type of legislation came after World War I. Characteristic of oath laws after the last war were New York's Lusk Laws of 1921, later repealed in 1923 after a series of persecutions. Of the 24 states now having such a requirement of teachers, 13 have passed their provisions in the two years 1931 and 1935.

The oaths required by such laws take different forms. Some require the teacher to swear to support the Constitution of the United States and the state; others require him to swear that he will support the Constitution and that he will faithfully discharge the duties of a teacher; some require an oath to support and defend the Constitution; others require the constitutional pledge plus a requirement to teach love, respect, and allegiance to the flag, government, and American institutions; and still others include prescriptions intended to prevent the teaching of specific theories of government or eco-

nomics. One form of this later type of oath law existed in the District of Columbia, until repealed by Congress in 1937, whereby teachers were required to swear at the end of each salary period that they had not "taught or advocated" communism. Federal funds appropriated for educational purposes may not "be used to pay the salary or wages of any person who advocates, or who is a member of an organization that advocates, the overthrow of the United States by force or violence." (Federal Security Appropriation Act, 1943, §703.) This statute has been interpreted by the Comptroller General of the United States to require a sworn affidavit. (20 Comp. Gen. 925.) The Commissioner of Education, whose appropriation comes under the Federal Security Appropriation Act, has interpreted the Act to require the oath from all persons paid in whole or part out of Federal educational funds granted to land-grant colleges (*q.v.*) under the Bankhead-Jones Act; to Federal vocational education programs and vocational rehabilitation programs; war-production workers (defense) training programs; the National Youth Administration program; and the Engineering, Science, Management, and War Training Program (ESMWT).

Coverage of the various loyalty oath laws varies from state to state. All the laws apply to elementary and secondary school levels, 17 to public normal school, 15 to public colleges and universities, 9 to private and parochial schools, and 11 to colleges and universities. But just what constitutes a violation of the oath has not been judicially determined.

The arguments for and against loyalty oaths cover a wide range. Basically the proponents of the laws seek to protect the schools from subversive, disloyal, and unpatriotic doctrines and to insure the loyalty of the teaching body; the justification given for singling out the teacher among all public employees is that society must be especially careful to shield its youth from the inculcation of seditious doctrines. The opponents of loyalty laws argue that to require teachers alone of all public employees to swear to such oaths is unjust and unfair discrimination; furthermore, they argue, such oaths tend to break down the academic freedom which should be permitted the teaching profession

LUNCH HOUR ACTIVITIES

if it is to do its task most effectively. The attitude of professional educators towards loyalty oath laws was expressed in a resolution adopted at the July 1936 convention of the National Education Association, and reaffirmed again in June of 1937, condemning "special loyalty oath bills." (See ACADEMIC FREEDOM; TEACHERS' LEGAL STATUS.)

LUNCH HOUR ACTIVITIES. It has long been recognized that living and learning are but different names for the same process. One effect of the realization of the true nature of the learning process has been the re-examination of subject-matter curricula, methods of teaching, and student activities in the light of their relation to the life needs of growing personalities. A corollary to this effect has been a growing awareness of the educative potentialities of extraclass activities. Student clubs, student self-government, excursions, and community projects have taken their place as vital elements in the enlarging concept of life learning. However, one important part of the school day generally has not been allowed to assume the importance it deserves. It is strange that in an education seeking to achieve social competence, the schools have generally ignored the possibilities of social training inherent in what has been traditionally the most social of all activities—eating.

It is a rule rather than the exception that no teacher assignment is more disliked than the "lunch-room supervision." The fact that it is called "supervision" is indicative of the spirit in which it is undertaken. The duty is observed in a wide variety of ways, from the supervision by a confirmed disciplinarian armed with a severe manner, a stentorian voice, and a strong-armed "sanitation squad," who enforces silence and cleanliness, to the soft-hearted little lady with hardened ear-drums who retires to a seat in the corner and corrects test papers.

Many schools, however, have made use of the lunch hour as a means of encouraging the good social habits associated with mealtime.

Tables are provided for groups of four, six, or eight to encourage the making of acquaintances. Sometimes teachers join these informal groups and act as host or hostess, or students take turns in acting as host or hostess. It has been found that the responsibility of enforcing habits of cleanliness, good order, and social cooperation can well be left to the students themselves through their own self-government organizations, such as the student council. In schools which have two or more lunch periods, sometimes no more than half an hour is allowed for each period. There is so little free time available after the students have eaten their lunch that it is difficult to plan lunch hour activities. If only one lunch period is provided in a school, that period is sometimes an hour or more in length and therefore adequate for both lunch and other activities.

The possibilities of social training are especially marked if the lunch period is long enough to allow for a half-hour or more of relaxation after lunch has been eaten. Student organized entertainment may be provided, announcements of significant student social events may be made, informal discussion groups may be formed, a community sing may be organized, a group interested in Spanish may practice everyday Spanish conversation or sing Spanish songs, etc. Some schools have special recreation rooms in which games are provided; chess, table-tennis, and checker tournaments are run by students; motion pictures are shown; and music is played for listening or for dancing. The scope of lunch hour activities is wide, and the potentialities of the lunch hour as an opportunity for exercise in positive social living and learning are great, especially if the students themselves undertake, through their elected councils, to organize the wide variety of socially and recreationally useful activities that can become a part of the lunch hour. Jacobson and Reavis give two reasons for student council activity in the program: (1) it presents a real problem which can be solved by pupils, and (2) it gives pupils some responsibility for the management of affairs which are closely related to the extracurriculum.

To accomplish these ends, the lunchroom must be made an attractive place; and time, facilities, and setting must work together to

LUTHERANS, EDUCATIONAL WORK OF

make the lunch period as helpful socially as it can be satisfying gastronomically.

According to one careful recent research the most common lunch hour activities in 356 schools are in order: games on the campus, loafing, resting, walking, and games in the building. A trend toward planned activities, however, has been gathering impetus in all sections of the country. J.E.G.

LUTHERANS, EDUCATIONAL WORK OF. Since the days of Luther and his co-laborers, education has been one of the chief factors in the development of the Lutheran Church. While Luther's educational classics (*To the Christian Knighthood*, of 1520; *To the Mayors and Aldermen of All the Cities of Germany in Behalf of Schools*, of 1524; *Sermon on the Duty of Sending Children to School*, of 1530) have in mind Christian education in state schools, the principles enunciated by him have rightly been applied wherever Lutheran congregations have been established in the various countries of the world. The principles which have always been stressed by the leaders of the Lutheran Church have been chiefly those insisting upon proper indoctrination of the young before admitting them to adult membership and the right to partake of the Eucharist. In fact, a notable *dictum* of Luther: "Where the Word of God does not rule, I advise no man to place his child," has become a slogan in Lutheran education.

The Swedish Lutherans were the first settlers of this faith to establish themselves permanently in America. That was in 1638. As soon as Fort Christina had been built, the colonists not only provided a chapel for church services, but also made arrangements for the Christian instruction of their children, their specific demand being that "all persons, but especially the young, shall be instructed in the articles of their Christian faith." In 1692 a petition was sent to the mother country which requested, among other things, the shipment of "one hundred handbooks and

spiritual meditations, two hundred catechisms, and two hundred ABC books."

The same zeal for Christian education was shown by the Lutheran group which settled in New York, although the undertaking met with certain difficulties because the Dutch government placed obstacles in the way of maintaining a separate school. In Albany the same situation was found. But among the Palatinates of the Hudson Valley independent schools were established shortly after 1700, and there are records of a log schoolhouse that was built at West Camp in 1710. Further immigration and natural growth brought about the establishment of other congregations and schools in this section of New York State.

But the real beginning of Lutheran education on a large scale took place in Pennsylvania after the coming of Henry Melchior Muehlenberg, often called the patriarch of the Lutheran Church in America. Muehlenberg was indefatigable in establishing Christian schools, not only in Philadelphia, but also in other cities. He was not ashamed to teach school himself, although it meant instructing children of 17 years and more in their ABC's. In one of his letters he states: "One week I teach school in Philadelphia, the next in Providence, the third in New Hanover." As a result of Muehlenberg's labors, the Lutheran school system of Pennsylvania expanded until it included a large part of the state, with hundreds of parish schools in operation in the first decades of the 19th century. It was only with the rise of the public schools and the increasing interest in Sunday Schools that the parish school movement lost its strength. It should be noted, also, that the Salzburgers in Georgia founded Christian schools for their children, and that the Henkels in Virginia acted as missionaries, teachers, and printers of Lutheran school books for a number of decades, their influence extending into Tennessee, Ohio, and some other states.

But a new impetus was given to the establishment of Lutheran parish schools by the so-called Saxon and Franconian immigrations, the former being directed to Missouri, the latter to Michigan. We are told: "Only a few days after the arrival of the first division of the immigrant colony in St. Louis a school was opened. The same took place in the other

congregations, in Perry County. If it was not possible to appoint a regular teacher, it was self-evident that the pastor, together with his ministerial office, also assumed the office of teaching." This idea has always actuated the Synodical Conference of the Lutheran Church in America. It has steadfastly maintained the necessity of Christian parish schools and of other agencies which would adequately supply the needs of children and young people in the field of Christian education. For a number of decades other Lutheran bodies of the Middle West also maintained parish schools and conducted normal schools for the adequate training of teachers, but the number of such institutions has materially decreased. Their place has, in many cases, been taken by Sunday Schools, which are now found in the majority of the parishes, Saturday Schools, summer schools or vacation Bible schools, released-time classes, and similar agencies. Whatever agencies and institutions may be found in the individual Lutheran parish, the aim of the Church is to give to every child an indoctrination which will be adequate for adult membership. The final step toward the accomplishment of this aim is found in the confirmation classes, in which children (and adults) are prepared for full membership in the Church, and especially the right to partake of the Holy Communion. The Lutheran Catechism and the Bible are the chief textbooks in such classes, and the rite of confirmation is attended by a great deal of dignity.

Secondary and higher education in the Lutheran Church of America is taken care of in scores of junior colleges and full colleges, a number of normal schools, and more than a dozen theological seminaries, which maintain high standards. A consistent effort is being made to raise standards in keeping with the advancement made in the field of secular learning, without endangering the character of the institutions as agencies of the Church. LYCEE—See FRANCE, EDUCATION IN.

LYING. Lying generally implies an individual's misrepresentation of facts or circumstances with the intention of deceiving others. It is one of the most frequent behavior prob-

lems among children and adolescents, and is somewhat more common among boys. Much of the lying of small children should not be classified as such, since it results primarily from their inability to make a clear distinction between fact and fancy. Usually, by the eighth year this confusion of truth and imagination diminishes, and it has practically disappeared by about the age of twelve.

Children find it difficult to understand that truth-telling standards are relative, and that what is regarded as a lie in one situation is considered tact in another. The inconsistent behavior of parents who punish children for lying, yet indulge in it themselves, makes the situation even more incomprehensible to the child. Other reasons for children's lies are the desire to escape punishment, to shield friends, to enhance prestige or to get attention; and, as a defense mechanism, to conceal feelings of inferiority.

In general, no anxiety need be felt over the so-called lies of small children. They might be reminded that some of their tales are the product of their imagination and did not really happen. Parental example is perhaps the most powerful influence in guiding the truth-telling standards of children. Punishment should not be so severe that the prospect of it frightens the child into lying. Opportunities to succeed in things that are within the range of their abilities will alleviate the necessity of lying to enhance the ego. Adolescents especially resent interference and often will lie to adults who seek to pry into their affairs.

Pathological lying occurs mostly among adolescents and adults and is frequently associated with sex delinquencies. Thus, girls will sometimes bring criminal charges against innocent men and then later admit in court that their accusations are fictitious. Pathological lying is usually associated with psychopathic or unstable personalities, and may or may not be amenable to treatment. R.V.M.

MANN, HORACE (1796-1859). Horace Mann is perhaps best characterized as an educational statesman rather than an educational philosopher; as a popularizer of the best educational thinking and practice of the mid-nineteenth century rather than as an original contributor to this thinking and practice. He was a leader in the Common School Revival in New England, as were Henry Barnard (*q.v.*), James G. Carter, and others.

His salutary influence in developing active enthusiasm for democratic popular education in place of apathy toward it, was exerted chiefly during his term of office as Secretary of the Massachusetts Board of Education 1837-1849. When he undertook this heavy task, the public elementary schools of Massachusetts were inefficiently administered by autonomous district boards, taught by untrained teachers, and provided with an emaciated curriculum. The children of the rich shunned them; their needs were met differently, in a totally distinct private school structure. Mann's animating credo was that public schools must be made as good as any schools can be made.

Chief Lines of Work. Tireless speaking circuits throughout Massachusetts were made, often under difficult conditions. Twelve annual reports were prepared and widely circulated, some of them having since become indispensable reading for students of the history of American education. The *Common School Journal* was published to keep the people informed as to the educational renaissance Mann was trying to bring about in their state. Institutes for the in-service edu-

cation of teachers were developed.

One of the most important phases of Mann's total program was his struggle to secure public support for the founding of state institutions for the preparation of teachers—normal schools. It was a key point in his credo that better schools necessitated better teachers, and that the preparation of better teachers was a public function and responsibility. By 1840, three years after he had assumed Office as secretary, Massachusetts had founded three publicly supported state normal schools, the first in the United States.

Mann's European trip of 1843 included a study of the educational practices of six countries. His observations, especially as presented in his Seventh Annual Report, helped American readers better to understand, by comparison and contrast, their own educational theory and practice. He was especially impressed by the Prussian-Pestalozzian system, which Prussia had set up, following the crushing defeat by Napoleon in the first quarter of the century. One of Mann's biographers states that if what he reported a century ago now seems commonplace, it is so partly because he brought it to the attention of Americans.

Specific Avenues of Influence. Mann, through his varied activities, may be rightly considered an important influence in the long line of apostolic succession which has brought about an enrichment of the American school curriculum, especially the elementary school curriculum. He stressed the importance of health education. Through his influence on Lowell Mason, he contributed to the establishment of music in the elementary curriculum. He saw the value of a richer literature experience for young children than the schools of his time made available. He helped spread the Pestalozzian emphasis on a geography beginning with the elementary school child's own environment.

As to the perennial problem of the best pedagogical approach to reading, whether

synthetic or analytic, Mann was one of the voices crying in the wilderness. The alphabetic approach had held its own since the colonial period. He preached the wisdom of beginning with a more meaningful unit of reading experience—in his case it was the *word* approach. Although later developments in the psychology of reading have led to the *sentence* and the *story* approaches as well as the *word* approach, Mann's suggestion that reading be introduced through meaningful units is still regarded as the basis for methods of teaching children to read. MANUSCRIPT WRITING—See HANDWRITING, TEACHING OF

MAPS, USE OF. The map is a plane surface representation, on a reduced scale, of the earth's surface or part of it, showing relative sizes and positions of geographical features. It is used generally and in such specialized fields, as geography, engineering, and military science; in navigation or astronomy it is referred to as a chart. The representation of globular surface configurations on a flat plane map causes distortion of scale, shape, area, and angle. To decrease distortion, orthomorphic map projections, showing land mass shapes truthfully as compared with their shapes on globes, and equal-area projections, giving any region on the map the same area as on a globe of the same scale, have been devised. Since it is impossible to represent truthfully both shape and area on one projection of a considerable area the map maker emphasizes one element while distorting in the least measure the other elements. To most practical geographers the truth of area is first and the truth of conformality next in desirability.

Few projections are truly perspective. *Perspective projections* involve placing a tangent plane against the globe or enveloping

it with a cylinder or a cone. A projection on the tangent element is then made of part of the grid system of the globe's parallels and meridians from either its center, as in the conic and gnomonic maps; a point on its surface, as in the stereographic maps; or a point external to its surface, as in orthographic maps.

In the *orthographic plane projection*, which represents a hemisphere, neither equal area nor conformality is obtained, the meridians and parallels being crowded toward the outer edges. It is used mainly in its oblique case for pictorial art purposes or for children in earliest stages of map study. The *stereographic tangent plane map* of the hemispheres, though partially conformal, is little used because of distorted areas near the edges resulting from the wider spacing of meridians and parallels there. The *globular projection*, arbitrarily spacing the lines equally, portrays suitably and simply the shapes and positions of land areas on a hemisphere. The *gnomonic type*, though little used for hemisphere maps because of marginal expansion and consequent distortion of both shape and area, is valuable when used in conjunction with Mercator's projection in plotting great circle air or sea routes.

The *Mercator projection of the world*, used for more than two and a half centuries, was designed to meet the difficulties of distortion involved in the central cylindrical and the equal-area cylindrical projections. The first type, projected from the center of a globe, yields a developed map with enormous expansion in high latitudes. The second elongates shapes in an east-west direction in high latitudes. In the Mercator map, the positions of the parallels are mathematically computed to result in a north-south expansion increasing at the same rate as the longitudinal expansion increases by projection. Though small areas are shown conformally, higher latitude exaggeration of area is, nevertheless, so great as to make it a misleading base map for showing industrial and other world distributions. For navigational purposes it has no rival since it alone shows all compass directions as straight lines.

The *conic projection*, supposing a cone tangent to the globe at a given standard parallel, is widely used, especially in mathematically derived or modified forms. The

MAPS, USE OF

cone, in theory, is unrolled or developed, revealing concentrically curved parallels and straight line meridians crossing parallels at right angles. It is relatively accurate for small areas of considerable longitudinal extent, such as Canada or Europe. For larger areas modified forms are used because of distortion due to distance from the tangent parallel. Among these, constructed on two standard parallels and yielding good shapes and equal—or nearly equal—area representation, the most useful are the *DeLisle*, the *Albers equal-area*, and the *Lambert conformal projections*. *Bonne's equal-area projection*, constructed on one standard parallel, gives good shapes for countries of limited longitudinal extent, such as France or Madagascar. The *polyconic projection*, based theoretically on a series of cones tangent at equidistant parallels, was developed by the United States Coast and Geodetic Survey and is used for the International Map of the World. Yielding good shapes and almost equal-area representation, it is one of the best for both small areas and those having considerable latitudinal extent, such as a map of North and South America.

In the *azimuthal*, or *zenithal projection* a plane is laid tangent to any selected center of the globe, usually one of the poles. The *Lambert azimuthal equal-area map* is useful for polar areas, continent maps, and hemisphere maps—all showing true compass directions from the center of the map.

The *non-perspective* or *arbitrary types* are projections in name only. These are mainly oval shaped, equal-area world maps with elliptical meridians converging at the poles. The *Mollweide homolographic projection* of the earth is an ellipse with the equatorial axis twice as long as the mid-meridian. In the *interrupted homolographic map* each continent has a separate mid-meridian thereby securing good shapes generally and decreasing distortion in high latitudes. Other oval projections, such as the *Aitoff* and *Eckert maps*, improve the shapes by curving the parallels or decreasing the convergence of the meridians. The *Sanson-Flamsteed sinusoidal equal-area projection*, whose meridians are sinusoids, is one of the best projections for hemispherical maps and for maps of equatorial regions, South America, Africa, and Australia. The *Goode interrupted homolosine equal-area projection*, being a combination

of sinusoidal from the equator to latitude 40 degrees north and south, and homolographic beyond these points, is probably the most useful and truthful map for representing world areal distribution of climatic, economic, and other elements.

Among future mapping projects are the completion of the International Map of the World by the principal nations and the much needed mapping of various world wide resources and activities.

For clarity, maps employ scales, relief schemes, and other graphic devices. The scale may be a graduated line, an expressed ratio between map lengths and earth lengths, or an inch-to-mile scale. Groups of contour lines, each connecting all points on the surface having the same elevation above sea level, are generally used to show surface relief. By their relative closeness of spacing the degree of slope is read. The United States Topographic Maps use contour lines. For less exact use hachures are employed. These short, straight lines vary in thickness and closeness with the slope and follow the directions of the steepest slopes at right angles to contour lines. Tints and light-and-shadow effects are also successfully used to show relief variation. Graphic devices are used to show areal distribution of geographic factors such as climate, production yield, cultural status, etc. Some, like crop maps, account for density of distribution. Others, like maps of religious status, do not. Among the usual devices are color or shade variations, cross hatching, dots, graduated circles, cubes, spheres, bar and pie graphs, square graph maps, and pictorial statistical maps. Isopleths, or isarithms, are lines drawn through points on a map having equal absolute or relative value. Instances are isohypses, (contour lines), isobaths, isobars, isotherms, isogons, and isohyets. Within the limits of isoplethic lines regularity of distribution cannot be ascertained.

Maps help to vitalize the study of geography and other subjects. Because of the limitations of maps, a globe should always be used in conjunction with them. The first concepts of children in the primary grades may well arise from maps they make in connection with field trips as part of their unit of work. The need for using direction guides, symbol, color, scale, and legend immediately arises and soon leads to consultation of pre-

pared maps. Mapping the neighborhood is a good preparation for later understanding of latitude and longitude. Map language must constantly be linked with children's experiences, direct or vicarious. Teachers must know and point out the limitations of the various projections, particularly the Mercator. Children ought not to have difficulty using the Goode homolosine equal area projection for study of areal distribution of geographic conditions.

Maps should be used not only for locational purposes and surface study but also for solving problems or introducing the study of a regional unit. They should be constantly at hand as a ready reference. The value of excessive drawing or copying of maps and even making clay maps is in question. Children should perform many exercises with previously prepared maps, in outline or otherwise, so as to increase their understanding of geographical relationships. Above all, interpretation of many kinds of maps is to be emphasized.

MARRIAGE, EDUCATION FOR—See FAMILY LIFE, EDUCATION FOR.

MARRIED STUDENTS. Marriage is not among the causes for which a person of school age may be barred lawfully from the public schools. Two supreme court decisions, one in Mississippi and the other in Kansas, commended the married persons of school age for desiring to attend school, and pointed out that the privilege of attending school should not be denied anyone within school age unless it is clear that the public interest demands exclusion. The matter is important because 18,317 girls from 15 to 19 years of age, of

whom half were 15, 16, or 17 years old, were married and attending school in 1930, which was probably a typical year in this respect.

MATERIALISM. Materialism is the theory that the elements of the universe can be reduced to one substance, matter, or matter in motion, of which the mind is merely a derived product. Included in this belief is the idea that laws run the universe, without any direction or supervision from a Divine Being. The materialist, in thus eliminating soul and a God, holds that education has no goals beyond those in this life. Also his emphasis on some form of material substance as ultimate reality leads him to stress the sciences and experimentation in the educational program. (See also MONISM.)

W.A.S.

MATHEMATICS, TEACHING OF. Over a long period three concepts have influenced curriculum and instruction in secondary school mathematics. These are: first, the disciplinary aim, relating to mental habits of precision, accuracy, and the like; second, the cultural values attendant upon appreciations and attitudes; and third, the utilitarian values of power to apply mathematics. In these concepts two important aspects of mathematics teaching are apparent: the *mathematical* or formal, concerned with the system and logic of mathematics; and the *social* or functional, concerned with the importance of its applications in the modern world. Of these, the former has until recently received the major attention.

Trends in Curriculum. The traditional college preparatory subjects—plane and solid geometry, algebra, and trigonometry, together

MATHEMATICS, TEACHING OF

with vocational mathematics such as business and shop mathematics—are those most commonly found in the curriculum. More recently, general mathematics in the first or last year has become important as an elective. Trends in the modification of content are in the main responses to four factors:

The change in the character of the high school population. With the great diversity of individual characteristics and purposes in the modern population of the high school, increased attention is being given to possible contributions in mathematics to the purposes of general education. So far as curricular modifications are concerned, adjustments have been limited to general mathematics courses either in the first or last year of high school, primarily intended for those not taking the college preparatory sequence. While there is still little agreement as to the nature of such courses, the trend appears to be toward the study of significant problems of the home, farm, shop, business and vocations, industry, safety, and health. Mathematics is thus considered as a means for developing efficiency in consumer or producer. The mathematical processes and operations to be utilized are those most suitable for studying the topics and acquiring understanding.

The reaction against crowding the entire arithmetic program into the grades. The general upward re-allocation of topics in arithmetic necessitates one of two adjustments: the entire ninth year must be given over to general mathematics, completing the arithmetic program and including such algebra and geometry as are applied to topics studied; or algebra is provided for students beginning the college preparatory sequence, with a parallel general mathematics course for non-college students.

Revisions in the theory of learning, particularly in the recognition of the need for many concrete experiences as the basis for development of abstract ideas of number and principles of mathematics. This factor has acted to direct emphasis to the social or functional aim. In this it has acted in the same direction as the fourth factor, namely, *the increasingly quantitative nature of social and vocational problems*, coupled with emergency demands for greater mathematical competence in the products of the schools. These factors have influenced the content in courses outside

the college preparatory sequence already mentioned. The college preparatory sequence, while not altered in form over a period of years, has undergone some modification in content through substitution of significant content for obsolete and useless materials.

In algebra, greater attention is being given to such functional topics as formulas, equations, graphs, and verbal problems, while there has been a decrease in emphasis on complicated algebraic techniques and factoring. In geometry, while training in logical thinking is still considered one of the major outcomes, there is less attention to scientific rigor and strict logic. There is a tendency to accept some obvious truths, and to verify others by experimentation. Some schools are utilizing geometry as an opportunity for a study of the nature of proof, carrying the techniques of critical thinking into non-mathematical problems such as the analysis of propaganda. Others stress the study of form, size, and position, considering logical thinking as only one of many important outcomes.

There is an increasing tendency to include a study of numerical trigonometry either with algebra or geometry, and to give some portions of solid geometry, either intuitively or with proofs, along with plane geometry. These adjustments are necessitated by the utility of these topics, and the fact that only a few students pursue mathematics beyond algebra and geometry.

Trends in Classroom Procedures. Recent trends in classroom procedures are mainly in response to increasing attention to individual differences, and the need for adapting instruction to those with relatively low mathematical aptitude. There is an increasing tendency to use visual aids, field trips, and other supplements to strictly verbal presentation. There is also an increasing use of long unit assignments, and other devices that make possible differentiated content and procedures. Recent experimentation has also revealed the importance of attention to vocabulary difficulties. In general, the greatest changes have been in the first year of the high school, and the least, in the college preparatory sequence. (See ARITHMETIC, TEACHING OF.)

Junior High School Mathematics, Teaching of Functions and Purposes. The program

MATHEMATICS, TEACHING OF

in mathematics in the junior high school has been well described by the National Committee on Mathematical Requirements as "an introductory, basic, exploratory course, in which the simple and significant principles of arithmetic, algebra, and geometry, statistics, and numerical trigonometry are taught so as to emphasize their natural and numerous relations". As they exist today, curriculum and instruction in junior high school mathematics represent the resultant of two movements, one in the field of mathematics, the other in secondary education. The former was an effort, undertaken at about the turn of the century, to make mathematical competence available to a larger proportion of secondary school students by adapting content and method to the individual and stressing utility and pupil interest. Beginning in England with the work of Perry, and continuing through the efforts of leaders in this country, this point of view may be traced through to the Report of the Joint Committee of 1940.

The second movement referred to is the junior high school reorganization. This was a response to the inadequacy of the procedures and methods of grades seven, eight, and nine in the traditional organization as it existed in the first two decades of the century. In view of the wide range of individual differences in the new school population, as well as the acceleration of social and economic changes, special provision is necessary at this level to render operative three important functions. The nature of junior high school mathematics is best understood in the light of these functions.

1. *Adaptation to individual differences.* These reach their peak in the years of the junior high school, since in the senior high school some selection occurs through specialization of curricula. Of particular importance to teachers of mathematics are differences in aptitudes, interests, plans, personality, experiences, and sex.

2. *Exploration and guidance.* These functions should precede differentiation and specialization. In mathematics it is particularly important that some exploratory experiences with advanced fields precede election of college preparatory courses.

3. *Transition.* Both in methods of teaching and curricular content there should be a progressive change from the guided and directed

activities of the grades to the independence and initiative of the high school and college.

In view of these functions, it is to be expected that aims which relate to disciplinary outcomes should hold a relatively unimportant place in the courses of study in junior high school mathematics, when compared with aims of senior high school mathematics. Disciplinary and cultural values appear, and are recognized in most modern text books, but they are relatively less important than provision for exploration and guidance, specific knowledges useful in life, and accuracy and facility in the fundamental operations.

Trends in Organization. The content and organization of the typical three-year sequence in junior high school mathematics show the influence of European practices, in that arithmetic, algebra, and geometry, together with some graphic representation and numerical trigonometry, are carried through the three years. Aside from the fact that this organization makes it possible to use whatever fields are necessary for studying the applications of mathematics in the social and economic environment of the pupil, there are other advantages in this organization. A longer period of maturation is provided for each field; easier and more concrete parts of each can be studied before the more difficult and abstract parts of any are attempted; the processes of other fields are available for assistance as difficult topics are studied in any one.

In grades seven and eight the emphasis on all three fields is more or less the same. In grade nine a diversity of practices appears. If the point of view of the junior high school is maintained, then the three fields are carried through the year with about equal emphasis, and try-out units of formal algebra, geometry, and trigonometry are introduced for exploratory and guidance purposes. The college preparatory sequence is then begun in the senior high school, in grade ten. The trend appears to be in this direction.

If the college preparatory sequence is begun in the ninth grade, the needs of the non-college group are cared for in one of three ways:

1. No further courses are made available outside the specialized college preparatory program.

2. Ninth grade algebra is offered for all

MATHEMATICS, TEACHING OF

pupils, in an endeavor at the same time to adapt the applications to the purposes of general education, and maintain standards suitable for college preparation.

3. Algebra is provided for the college preparatory group, and general mathematics for the non-college group.

Trends in Content. The general practice, both in textbooks and courses of study, is to recognize the several fields of mathematics as distinct. There is little tendency to fuse the fields of arithmetic, algebra, and geometry. There are differences, however, in the bases for organizing the content of the courses. The differentiation lies in the practice, on the one hand, of using mathematical topics or processes as the basis of organization, as *percentage*, *formulas*, or *similar figures*; or on the other hand, of organizing content around economic topics, as *travel*, *transportation*, or *production of goods*. When this latter plan of organization is used, the criteria for selecting the processes to be applied are the readiness of the pupil to utilize them effectively; their value in contributing to the understanding of the social and economic problems; and the necessity for developing a logical sequence in mathematical operations.

The arithmetic incorporated in the sequence has two main purposes, both of which are being accentuated by the upward re-allocation of topics in the grades. One is to complete a remedial program of skills in the operations. The other is to study important social topics in which arithmetic is the means of acquiring understanding. Every course of study in junior high school mathematics includes business topics, such as banking, insurance, and investment. Many include a study of government, and there is an increasing tendency to utilize arithmetic as a means for developing consumer intelligence. There is a trend toward grouping smaller topics such as budgeting, accounts, earning, and the like, under a general heading such as *Managing the Family Income*.

Algebra, in grades seven and eight, includes the use of literal number in formulas, the solution of simple equations intuitively (by using "common sense"), simple operations with monomials, fundamental concepts like *formulas*, *similar terms*, and *coefficient*, and often simple uses of directed numbers.

These are introduced in realistic problem situations, and the emphasis is on significance, rather than on theoretical treatment. The algebra content of grade nine, as we have seen, varies in different plans of organization.

The geometry of the junior high school rarely touches on demonstration of theorems and the nature of proof, except for purposes connected with exploration and guidance. It is rather concerned with development of concepts, facts, and relationships of geometry through intuitional and laboratory procedures. Several general types of activity have been defined:

1. Intuitive geometry, used when the pupil looks at a figure and discovers the obvious, for example, the equality of vertical angles.

2. Experimental geometry: fitting the angles of a paper triangle together to discover the sum.

3. Observational geometry, which sensitizes the pupil to the geometric relationships in his environment.

4. Geometric constructions, both with ruler and compass, and with drawing instruments.

5. Simple demonstration, through informal proof of simple facts: deducing the sum of the angles of a quadrilateral, when the sum of the angles of a triangle has been established.

MATRICULATION. Matriculation is the procedure by which a person not before enrolled in a given college or university supplies the necessary information and otherwise satisfies the requirements for enrollment as a student. This procedure may be long and complicated and may include giving any of the following information: applicant's full name, date and place of birth, home address; parent's name, address, occupation, and education; name of secondary school attended, dates of attendance, and transcript of record; physician's statement concerning applicant's health; character recommendations; religious affiliation; information about other colleges attended (if other colleges were attended, such information as official transcripts of records and recommendations from those colleges); college course which the student intends to pursue. Frequently admission, placement, or college aptitude tests are required as part of the matriculation requirements. (See LIBERAL ARTS COLLEGE.) R.A.K.

MEASUREMENT IN EDUCATION. Measurement in some form has doubtless always existed in education. It seems inevitable that teachers should attempt in some way to determine and to describe the progress of learners. For a long time, however, the rôle of measurement in education was recognized

only vaguely, and the techniques employed were quite informal and usually highly subjective. In recent years great progress has been made toward clarifying the functions of measurement and toward improving the instruments used.

Three functions of measurement may be differentiated; namely, the administrative, instructional, and research. Schools have long used measurement for the classification and promotion of pupils. The modern school emphasizes other administrative functions of measurement, notably in vocational and educational guidance, in evaluating various aspects of the school program, and in public relations. Classroom teachers find many instructional uses for measurement. Probably the most important of these is educational diagnosis and remedial instruction. Teachers recognize the dependence of correction upon diagnosis, and rely upon a variety of measurement techniques for locating the weaknesses of individual pupils. It has also been shown that the measurement employed motivates learning, and affects both the amount learned and the study procedures employed. Educational research relies upon measurement for determining the initial status of the experimental and control groups and for establishing the comparative progress made.

It is important to recognize a distinction between direct and indirect measurement. Measurement may be described as direct when it calls for the functioning of the ability or trait, or is arrived at by direct comparison of the unit with the thing measured. Physical measurement of strength, speed, height, and weight are examples of direct measurement, while the measurement of temperature is indirect.

Many distinctly educational measurements are indirect; that is, they infer the existence of one trait or ability from the measurement of another. It is well known that intelligence tests, for example, seek to measure learning capacity indirectly by measuring directly what the pupil has actually learned. The quality of a school is often measured indirectly in terms of the adequacy of its physical plant and the training and experience of its staff rather than in terms of its finished product. Even the ordinary measurement of educational achievement commonly involves an inference. For example, the pupil's ability

to read connected material under the normal conditions of life is usually inferred from his ability to answer questions based upon unconnected paragraphs read under the artificial conditions of the schoolroom. The validity of indirect measurement obviously depends upon the correlation of the abilities actually measured with those whose existence is only inferred.

At the present time, tests and examinations (*q.v.*) of a wide variety of types constitute the most important instruments of measurement. The effective use of both standardized tests (*q.v.*) and nonstandardized tests, whether essay examinations (*q.v.*) or objective tests (*q.v.*), depends upon a clear understanding of their comparative advantages and limitations. Other instruments include questionnaires, rating scales, and interviews (*qq.v.*). Recently the term *evaluation* (*q.v.*) has been used to suggest a more comprehensive concept of measurement which attempts to appraise the whole personality of the child and emphasizes the less tangible outcomes of instruction, such as attitudes, appreciations, interests, ideals, and points of view. (See such topics as *EVALUATION*; *GUIDANCE*; *RESEARCH, EDUCATIONAL*; *STANDARDIZED TESTS.*) C.C.R.

MECHANIC ARTS—See **INDUSTRIAL ARTS EDUCATION**.

MECHANICAL ABILITY. "Mechanical ability" refers to the general capacity of a person for dealing with concrete objects. The correlations between verbal intelligence test scores and those of mechanical aptitude are low. This has led to a distinction being drawn between abstract intelligence and mechanical or concrete intelligence. Tests of abstract intelligence are largely verbal in content while tests of mechanical aptitude are in large measure performance tests involving manual skill and insight into the relations of objects and parts of objects (especially mechanical objects) to each other. This apparent independence of mechanical ability has led some educators to regard it as a special ability and

to suggest that it is probably a specific innate capacity. However, since school practice has in the past emphasized verbal learnings and neglected the development of mechanical aptitude, the lack of mechanical ability may be due in many cases to lack of interest and education in mechanical activities. Consequently, while the use of mechanical aptitude tests may serve to discover persons who are especially capable in such activities, the failure of others to make satisfactory scores may be a result in large measure of the non-mechanical bias of their elementary and secondary education. Educators may well extend to children and youths wider opportunities in such fields as drawing, construction, and experimentation in mechanics with the expectation that the average mechanical ability of both girls (who have been especially neglected) and boys will be increased. (See *APTITUDE.*) W.F.B.

MECHANICAL SCORING OF TESTS.

Machines are available for scoring objective tests of the true-false, multiple-choice, and matching types. Separate answer sheets are provided on which the choice of answer is indicated by a pencil mark. This mark is electrically conductive and, when the answer sheet is placed in the machine, is used to close a circuit, the resulting flow of electricity being recorded as a measure of the number of correct or incorrect responses.

The use of the machine reduces the possibility of errors in marking caused by carelessness or fatigue, shortens the time it takes to assemble data on test results, and eliminates the drudgery of the correction of test papers. The major shortcoming of mechanical scoring of tests arises from the fact that present machines can correct only a very few types of questions. The convenience of mechanical scoring may thus encourage the use of such types of questions as the multiple-choice question even in situations where other types of new-type questions and essay questions may be more appropriate. (See *ESSAY EXAMINATION*; *OBJECTIVE TESTS* and *EXAMINATIONS.*) J.J.

MEDIAN—See **CENTRAL TENDENCY**.

MEDICAL EDUCATION. The United States Constitution provided no supervision over medical education or medical practice, but left this to the individual states. The first

MEDICAL EDUCATION

period in medical education was that of apprenticeship, when young men assisted busy practitioners in their daily work and started to practice either without a degree or with authority conferred by a local medical society or college. This was followed by the establishment of the private or proprietary medical school relying for support largely or solely on the fees and good will of the medical students. The lack of legal safeguards made it easy for any group to open a medical school and grant degrees. In 1906 there were 162 medical schools in the United States. After the establishment, in 1904, of the American Medical Association Council on Education, medical schools were inspected and graded according to their degree of excellence. The number of medical schools decreased and their standards rose. Medical schools now share in the educational and financial support of universities, are sometimes privately endowed, and are equipped with good laboratories, well trained teachers, efficient methods of instruction, and close dispensary and hospital affiliations.

The premedical student should be aware of the importance of a well rounded general education as a preparation for the study of medicine and should not limit himself to scientific courses. The minimum requirement since 1918 has been two years of college work, including English, theoretical and practical courses in physics, biology, and in general and organic chemistry—usually completed in institutions approved by the Association of American Universities, North Central Association of Colleges and Secondary Schools, Southern Association of Colleges and Secondary Schools, Middle States Association of Colleges and Secondary Schools, Northwest Association of Colleges and Secondary Schools, or New England Association of Colleges and Secondary Schools. While there is no stated rule prohibiting acceptance of applicants from schools not approved by one of these accrediting agencies—selection is based on quality of preparation, regardless of where obtained—officials give preference to those who have prepared in institutions known to conform to accepted standards.

Since success in the medical curriculum demands more than average intelligence and industry, the college student who cannot place himself in the upper third of his class will

usually find it inadvisable to start on a medical career. The selection of a student depends on the results of an interview with members of an admission committee or one of its regional representatives, in addition to an evaluation of the student's curricular and extracurricular record, his percentile rating in the Medical Aptitude Test, as well as carefully prepared confidential appraisals by teachers who know him personally.

Although most accredited medical schools require more than the minimum two years of preparation, their requirements are not rigid in the matter of elective courses. To some extent the candidate should be governed by his own chief interests and the intellectual stimulus to be derived from the work. A literary background is of inestimable aid to his career. In general, he should prevent duplication by avoiding courses in subjects that are included in the medical curriculum.

The standards set for entrance to medical school are reflected by the fact that only slightly more than one per cent of all students admitted to medical schools in 1941-42 had less than three years of college work.

The standard medical curriculum requires 3,600 to 4,400 hours for its completion. The work is grouped as follows:

Anatomy, including embryology and histology
Physiology
Biochemistry
Pathology, bacteriology, immunology
Pharmacology
Preventive and tropical medicine, public health
Medicine
Pediatrics
Surgery
Obstetrics and gynecology

The general trend in enrollment and graduation in medical schools for the period 1905 through 1942 is shown below:

Year	Schools	Students	Graduates
1905	160	26,147	5,606
1910	131	21,526	4,440
1915	96	14,891	3,536
1920	85	13,798	3,047
1925	80	18,200	3,974
1930	76	21,597	4,565
1935	77	22,888	5,101
1940	77	21,271	5,097
1942	77	22,031	5,163

All but six of the 77 medical schools in the

MEDICAL EXAMINATION — MEMORY

country admit some women students, and the Women's Medical College of Pennsylvania teaches women students exclusively.

Women in Medicine in the United States

Year	Women Students	Percentage of All Students	Women Graduates	Percentage of All Graduates
1905 ..	1,073	4.1	219	4.0

MEMORITER METHOD. A method of teaching that makes its basic appeal to memory; arbitrary rote learning. The term is now used mainly in a derogatory sense. While it is granted that sound education requires the retention of many facts and principles, these must be imbedded in a matrix of meaning to be educative. (See **CATECHETICAL METHOD.**) W.R.

MEMORY. Memory is involved in practically everything we do and say and feel. In this sense it may be defined as past experience which involves present experience. The problem of how we remember overlaps largely the problem of how we learn. The use of the noun *memory* may stem originally from the belief that memory was some kind of special substance or specific structure or "faculty" which allowed the act of remembering to proceed. Since the belief in specific

mental faculties has been largely discarded, many psychologists prefer to discuss memory as the act of remembering.

Several forms of remembering can be distinguished: (1) the recognition of a present event as similar to or different from a past event, (2) reminiscence, (3) the reproduction in response to a direct demand of a past event exactly as it was experienced, (4) the giving in answer to a familiar situation of a response which was learned originally as the response to an identical or closely similar situation, (5) the summoning from the past of learnings pertinent to the solution of a present situation which is novel to a greater or lesser degree.

The manner of learning affects the ability to remember after a lapse of time. It has been found that even things which must be learned by heart so that they can be recalled later exactly as learned (e.g., poetry, a dance pattern, a musical selection, the date of an event, etc.) are remembered better if understanding as well as repetition was included in their learning. Where remembering of the fifth type described above is required, it has been found that rote learning is largely ineffectual. The essential process here is that of grasping the meaning of a rule, definition, paragraph, demonstration, situation, or any other learning experience. For understanding of the meaning makes the experience available for use in new situations as they arise. Rote memorization is thus reduced to a minimum in modern schools. Verbalization of subject matter which is understood is, however, an aid rather than a hindrance to remembering; e.g., the verbalization of a procedure, of a generalization, of a scene, or of an ideal.

The capacity to remember is affected also by the degree in which the material was mastered in the first place, the nature of the materials (meaningless materials being forgotten faster than meaningful ones), the affective or emotional aspects of the materials or situations both at the time of learning and the time of recall, the individual's interests and purposes, and the individual's level of intelligence. The capacity to reproduce with rote recall a series of digits or nonsense syllables increases throughout childhood into late adolescence, and the capacity to remember logical materials follows a similar course,

probably continuing its development to a later age.

While the various forms of remembering distinguished above are positively correlated to a sufficiently high degree so that a test using any one form only will usually correlate well with a test using another form only, the ability to remember a fact in the form in which it was learned does not imply the ability to recall that fact for solving a new problem. Recognition is similarly related to recall, so that a true-false or multiple-choice test *may* produce results which are better than would be shown on a short-answer or completion test of matching items.

The curve of forgetting, which indicates the percentage of what is retained of the original learning after various periods of time have elapsed, differs in different cases but it commonly shows a comparatively rapid initial loss followed by a very slow rate of continuing decrease. The degree of initial loss pictured by the famous Ebbinghaus curve was very great, being considerably over fifty per cent after a single day. It has been found that this initial loss is less the better the material is learned in the first place. Different school subjects show different rates of forgetting. Specific factual material in science is forgotten faster than scientific explanations and generalizations. As a matter of fact in cases where reasoning is involved, improvement rather than loss is often shown over a period when there is no study in that area. The Ebbinghaus curve was based upon nonsense material. The more the subject matter resembles nonsense to the learner, the more his curve of forgetting will resemble the Ebbinghaus curve.

The curve of forgetting indicates the quantitative but not the qualitative aspects of forgetting. We not only forget; we remember things inaccurately. What is remembered even with a feeling of great certainty may be quite different from the original happening or learning. The emotions of the present are often projected into the past which is then schematized in terms of those emotions. Sometimes this inaccurately reconstructed situation is then itself memorized and becomes the basis of future remembering. Even where strong emotions are not concerned the process of remembering-forgetting is still dynamic. There is a tendency both to remember things

as simpler than they were, and to elaborate to a considerable degree. Where the situation actually observed had an unfinished quality about it, it is apt to be remembered with the inclusion of some item which gives it a more completed character. Incoherent features of a scene are often forgotten or rearranged so that the event is remembered as a logical pattern. What is remembered is also more balanced and symmetrical than what actually was seen or heard. These generalizations are borne out by the testimony of witnesses who have sworn to tell exactly what they saw and heard, and by laboratory experiments of the perception of visual forms and of the retelling of stories.

For the educator the problem of remembering is the problem of efficient study and learning. The effort to recall (or recite) material which has been learned only partially is itself an aid to memorization. Such recall, when it can be compared with the original, will at the same time allow inaccuracies of remembering to be removed. Review of material before too much has been forgotten will bring the learning back to a level of mastery which will result in a slower rate of deterioration. However, the best technique for halting or slowing up the process of forgetting is the continuous use of the learned facts in new relationships.

MENTAL AGE—See INTELLIGENCE QUOTIENT.

MENTAL CONFLICTS—See CONFLICTS (MENTAL AND EMOTIONAL).

MENTAL DEFICIENCY. *Mental deficiency*, also known in the United States as *feeble-mindedness*, is an inadequacy of mentality or intelligence, which in some cases may be so great as to amount almost to a lack of

MENTAL DEFICIENCY

mentality. The inadequacy is measured in terms of some standard, usually allowing different degrees of inadequacy to be recognized. The British Mental Deficiency Act of 1927 uses a qualitative standard to distinguish three grades of mental deficiency which is generically described as "a condition of arrested or imperfect development of mind existing before the age of eighteen years whether arising from inherent causes or induced by diseases or injury." Persons of the lowest grade of mental deficiency, the *idiots*, are defined as those "so deeply defective in mind as to be unable to guard themselves against common physical dangers." The next grade of mental defectives, the *imbeciles*, are described as "being incapable of managing themselves or their affairs or of being taught to do so," while the highest grade defectives, termed *feeble-minded* in England and *morons* in America, are those whose mental defectiveness is sufficiently pronounced to "require care, supervision, and control for their own protection, and the protection of others, or, in the case of children, that they, by reason of such defectiveness, appear to be permanently incapable of receiving proper benefit from the instruction in ordinary schools."

American psychologists have voiced dissatisfaction with these descriptions partly because many cases of *dementia* (involving decline in mental ability due to insanity) can be classed as *amentia* (mental deficiency), under the definition of the latter in the British law. *Amentia* and *dementia* are sometimes difficult to distinguish in young children unless an accurate case history of the child's development can be obtained. Because the treatment differs for *amentia*, occurring alone, *amentia* and *dementia* occurring together, and *dementia* occurring alone, it is important to distinguish between the two types of abnormality.

On the whole, American psychologists favor using the average I.Q. (*q.v.*) obtained on several standardized intelligence tests as one of the main criteria of mental deficiency, though warning that the final decision as to whether or not the person is mentally deficient, and to what degree, should be made only by trained psychologists and psychiatrists, especially in those cases where the classification leads to such an important de-

cision as institutionalization. State Education Laws commonly specify an I.Q. range from which the children to be taught in special classes for the mentally retarded are to be drawn. The New York State Education Law excludes idiots (below 20 or 25 I.Q.) and imbeciles (20 or 25—50 I.Q.), limiting the range for special-class placement to children with I.Q.'s between 50-75 I.Q., as well as specifying a range between a mental age of 5 years and 10 years. A few states put the lower limit at 35 I.Q.; and some put the upper limit at 70 I.Q. (Note: These I.Q.'s are all based on the 1916 revision of the *Stanford-Binet* test. The new revision of the *Stanford-Binet* and the revision of the *Kuhlmann-Binet* for younger children, now called the *Kuhlmann Tests of Mental Development*, may lead to slightly different I.Q. limits.) Some teachers deplore the setting of a mental age of 5 as the lower limit for special class education, contending that this means that a child with an I.Q. of 60 must remain in regular classes until he is eight and a half years old, even though he cannot profit from the instruction given that class. Others argue that the regulation is a wise one, in that the validity of the tests for children with mental ages below five or six is open to question.

The proportion of mentally-deficient in the population depends upon the definition used. Using the new revision of the *Stanford-Binet* Intelligence Test, it is theoretically estimated that about 2 per cent of the population have I.Q.'s below 70, while almost 4 per cent have I.Q.'s below 74. The United States Office of Education states that mentally-retarded children constitute two to five per cent of the juvenile population. New York State has estimated that about 2 per cent of the children fall within their 50-75 I.Q. range for special classes. The number of individuals with a given I.Q. decreases as one goes down the scale to greater and greater deficiency; thus there are fewer individuals with I.Q.'s of forty than with I.Q.'s of fifty. Since the lifespan of low-grade defectives is less than that of normal individuals—their mental deficiency being combined with marked physical deficiency, particularly lack of coordination—the proportion of low grade defectives in the general population becomes less as the chronological age of the group that is being measured increases.

MENTAL DEFICIENCY

The physical factors involved in mental deficiency are much more obscure for high grade mental defectives than they are for idiots. Though intelligence is no longer considered to be a simple genetic trait, mental deficiency, in those cases where it seems to have been present from birth and where there is no record of fetal or birth injury, is usually attributed to heredity. The inherited traits which contribute to mental deficiency are thought to vary with different individuals.

From a practical point of view, the problem for the educator resolves itself into the question of whether specific cases of mental deficiency can be treated so as to bring about a higher degree of mentality. Certain types of mental deficiency which have been distinguished on a basis of a specific type of physical deficiency or disease receive medical treatment, often successfully. For example, *cretin* idiots, whose thyroid secretion is inadequate, have shown considerable mental improvement, especially in some cases, when thyroid feeding was begun early and continued regularly. In cases where there has been successful treatment of epilepsy, the accompanying mental deficiency has also been known to improve. In such cases the individual may, within a calendar year, gain even more than one mental year on intelligence tests until he has caught up to the normal level. All sorts of medical and nutritional therapeutic measures are being experimented with, but on the basis of present evidence and techniques, there is little hope that such measures will raise the I.Q. considerably, except in a few cases. However, even ten or fifteen I.Q. points of improvement may mean that functional intelligence is raised sufficiently so that the child can make better social adjustments than heretofore. It may even mean the difference between institutionalization and non-institutionalization.

Whether treatment other than medical and nutritional will lessen mental retardation is of even more interest to the teacher. Here again improvements of a non-spectacular nature have been reported to accompany the provision of a better social and educational environment than the aments had previously experienced. Of considerable interest is the finding that though the I.Q. of the feeble-minded usually declines with age, children

who are given special education or who are placed in better environments maintain, and may even improve, their I.Q. Particularly suggestive for teaching methods, even though the number of subjects in the experiment were too few to warrant the making of scientific conclusions, were the results of Kephart who found significant changes in the I.Q.'s of institutionalized high-grade moron (I.Q. range 60-75) and borderline children (I.Q. range 75-90) when the teaching emphasized the activity of the learner, his ingenuity, initiative, and original planning, rather than the finished product. Since many books on the education of the mentally-retarded and slow learners still advocate drill and imitation as the best methods, Kephart's conclusions for teaching are challenging. Curriculum guides for mentally-retarded children which have been prepared by the United States Office of Education also recommend an experience curriculum related to the child's immediate interests and environment rather than drill on the "minimum essentials." Necessarily, the content of the curriculum for the mentally retarded, the speed with which they are expected to learn, and the abstract conceptions which they can build upon their direct experiences will all vary from what is provided for and expected of normal children. Modern theory, however, shows a definite trend towards favoring the same general type of teaching methods for high grade imbeciles and morons as for normal children. It must be remembered, however, that the differences between idiots and morons and between imbeciles and high grade morons are even greater than the differences between morons and normal individuals. The great range of individual differences among these handicapped children must be borne in mind when it is said that mentally deficient children are retarded in physical development, that they have defective sensory capacity, that they lack the ability to concentrate, that they suffer from faulty retention and recall, that their imagination and reasoning are feeble, that they cannot anticipate consequences, that they have great difficulty with symbols, that their vocabulary development is poor, that they lack the ability to control and inhibit emotional responses, and that they are easily swayed by others. The education of the best among them must not be based on the quali-

MENTAL HYGIENE

ties so observable among those lowest on the scale of intellect.

Education for the mentally deficient should consist more of direct experiences and less of verbal teaching, even when the verbal teaching is oral in nature. Language handicap is one of the most pronounced weaknesses of these children, and though morons can be made by systematic drill to memorize all kinds of verbal facts, this learning does them little good if the words remain meaningless to so great an extent that the verbal knowledge cannot be put to any use. It has often been said that mentally retarded children can learn the same things that normal children of equal mental age can. This statement is not always true, since the normal child of five is much faster in his responses, and often in insight, than is the ten-year-old child with a mental age of five years. Moreover, because of the very small amount of progress that the child with a low I.Q. can make, it is foolish to teach him the beginnings of processes or informations which are valuable only when considerable mastery has been obtained. This is true with regard to reading, arithmetic, and spelling on which backward children usually spend an amount of time entirely disproportionate to the usefulness in their adult life of the learning which such children can acquire in these areas. As a guide to what should be taught, the final mental age which each child can reach should be taken into account and experiences should be arranged for him which will eventually bring him to as great a degree of self-responsibility as possible. From all that he is capable of learning, there should be selected those learnings which are necessary for his protection and safety, which will help in his social adjustment, which will lead to a vocation, and which will keep him generally happy and well-adjusted.

The emphasis on the social development of the mentally-retarded child is seen in the Vineland Training School, New Jersey, where Doll has devised a special scale for the measurement of social maturity, *The Vineland Social Maturity Scale*, which uses the technique of recorded observation by trained workers. The set of behaviors listed for each age level will give teachers some idea of how to evaluate the progress of the mentally-handicapped in areas other than the subject-matter areas in which the bulk of the achieve-

ment tests for the normal children lie. With proper education and attention to their relatively strong points, even low-grade morons have been able to turn into self-supporting men and women of sufficient stability to need little help from others. However, since unscrupulous persons are ready to take advantage of the mentally-retarded individual at those points where the latter has not sufficient intelligence to think problems out properly, it would be well for schools to help special class children to learn which people they can safely go to for advice and to develop the readiness to ask for such advice when needed. (See INTELLIGENCE; SLOW LEARNER.)

MENTAL HYGIENE. Mental hygiene is an approach toward human adjustment and achievement, concerned with preventing emotional maladjustments and enabling individuals to operate at their most efficient levels. The earliest concept of mental hygiene focused on the treatment of mental illness, but there has been over the past two decades a shift of emphasis to the prevention of mental illness and the adjustment of individuals to their environment. Its practice is based largely on the body of knowledge contributed by the various sciences that promote the understanding of human behavior, but while much of mental hygiene rests on a scientific basis, there remains a significant contribution derived from the experiences of those who have developed the art of guiding the growth, development and adjustment of individuals. Through its preventive and therapeutic aspects mental hygiene has universal implications, for while the study and treatment of maladjusted individuals is the responsibility of the trained professional person, the prac-

MENTAL HYGIENE

tical use of mental hygiene concepts is the concern of everyone.

Acquisition of a mental hygiene point of view involves an awareness of the implications of behavior, an interest in the reasons for conduct, and a knowledge of the far-reaching effects of human relationships. It is of particular importance for the teacher who recognizes the educative function as not merely the imparting of subject matter but involving a much broader area, that is, helping the child to learn how to live as a social being in an environment which will make demands of him, and to which he must adjust; to develop healthy mental attitudes; to make reasonably full use of his physical and mental endowments; and to derive personal satisfactions and happiness. An interest in the child's motivations and in his reactions as an individual with his own differences enables the teacher to direct the child's educational experience so that he can enhance or establish his emotional security, his feelings of adequacy, and his self-worth.

The mental hygiene orientation implies that we look upon the child as a functioning whole, whose separate attainments and functions cannot be isolated without disturbing the pattern of the whole. His behavior is purposive, the result of not one but many factors. The child's behavior is his attempt to meet a situation, to handle his needs—in effect, to make an adjustment to the environment. The behavior may or may not be socially acceptable, depending largely upon the quality of the child's personality development. In considering conduct or behavior we look beyond the overt or manifest act and seek the underlying reasons for it. We endeavor to understand what it represents and why it has happened, rather than focus all our attention and remedial efforts on what has happened. Thus, in the child presenting deviations from accepted or normal behavior, the behavior should be looked upon as symptomatic of his conflicts and difficulties. As we go into the causes of the behavior we uncover significant factors responsible for the way in which the person is reacting. At birth, the child is endowed with a capacity for growth and development. He is also the possessor of certain inherited physical and intellectual potentialities and limitations. The way in which these will affect the child depends in large part

upon his early life experiences in the home and in the school. Although the family experiences play the greatest rôle, the school has a significant effect upon the child's emotional adjustment.

Fundamental to the child's ability to achieve emotional adjustment is the development of emotional security. This state is characterized by a feeling of safety, of belonging, of self-worth, and gives the individual an assurance regarding his ability to cope with whatever situations may arise, whether they be adverse or not. It is an outgrowth of the parent-child relationship and is nourished by the love and expressions of love, such as fondling and cuddling, that the baby receives from the parents, establishing in him an awareness of acceptance and belonging in his family. Its strength depends upon the ability of the parents and the other adults who play an important part in his life to treat him as an individual with respect for his rights as a person, to help him develop initiative and self-reliance, always with an awareness of his physical, emotional and intellectual limitations, but giving him the experience of learning that behavior which brings satisfactions, physical as well as emotional, must change as he grows older. He must be given the opportunity for successes, approval, and status development. This psychological weaning requires wise judgment, for too sudden thrusting of responsibility and self-dependence upon the child whose maturation level does not warrant it is just as destructive emotionally as is the overprotectiveness and infantilization by parents who are afraid to let their children grow up. Parents, too, are reacting to their own life experiences, and may because of their own needs and conflicts be unable to give the child the security he needs for healthy personality development.

The child whose emotional needs have been satisfied is able to obtain satisfactions and utilize his abilities effectively. He learns to handle situations with fairly consistent and appropriate behavior. He is reasonably free from mood swings, that is, he is neither unduly elated nor depressed. In other words, he is able to adjust to his environment. On the other hand, although the child whose needs have not been met adequately may be able because of fundamental stability to maintain his emotional equilibrium, most individuals

need the help of various adjustment mechanisms to achieve this equilibrium. These may consist of aggressive acts, rebelliousness, anger episodes, fear reactions, timidity, daydreaming, seclusiveness, overdependence on adults, rationalizations, compulsive acts, and a host of others. The child who feels inadequate and inferior may try to compensate for this and gain status with the group by becoming belligerent and aggressive, or he may find the situation too traumatizing and pull away from it through timidity and daydreaming. Phantasy then replaces reality because phantasy is far more pleasurable. An inability to establish good social relationships and gain class acceptance may precipitate similar behavior patterns. These are not consciously adopted by the child but develop out of his need to effect an adjustment, which though it be a poor one is nevertheless a solution of his problem. The seriousness of these reactions from the point of view of mental health, has to be judged individually. No one method can be universally condemned or justified. The important question to answer is whether *they result in maladjustments which prevent a recognition on the part of the individual of the reality factors.* Some adjustment devices, such as a rationalization about the value and pleasure of handicraft which enables a crippled child to engage in it with satisfaction instead of feeling the humiliation and inferiority engendered by watching a group of boys playing baseball, are valuable means of promoting emotional stability.

The aim of modern education and of mental hygiene is essentially the same: a well-adjusted child, integrated with his environment, making good use of his abilities and utilizing his potentialities. His education is not solely a preparation for adult responsibilities, but a process which aids him in his day-to-day living, recognizing that his ability to handle his adult adjustment depends almost completely upon how well he has learned to handle his childhood and adolescent adjustments. It is now accepted by modern educators that the development of habits and attitudes which will facilitate the child's total life adjustment is more important than the traditional emphasis on specific skills and information. It has been found that unmotivated acquisition of information makes but a transient impression on the child and that the

gearing of subject material to his natural interests and capacities, integrating it with the rest of his experiences, is far more effective. The modern school is aware that a child's learning ability cannot be isolated from his emotional status. The child, worried about something which has happened at home, beset with fears, or feeling completely inadequate, is often not going to be able to learn. Advice, scolding, or drilling will not remedy the situation. Knowledge of the factors producing the difficulty is necessary, plus a school situation reasonably free from the procedures which promote maladjustments.

The elimination of tensions in the classroom, together with the development of a teacher-child relationship based not on fear of authority but on awareness of a friendly, interested, impartial adult, not only prevents feelings of personal inferiority from developing but also sets the pattern of authority relationships.

Emphasis upon making the educational program an integrated part of the child's life utilizes the fact that from the day of his birth through childhood, adolescence, and adulthood, the individual is being acted upon and influenced by every aspect of his environment, and in turn is reacting upon it. It is therefore necessary to incorporate as much as possible of the child's experiences into the curriculum. School work then becomes part and parcel of everything else he does. It is carried over into the home, and parents are co-operatively involved in it. Parent interest in the mechanics of what the child is doing in school, using the family as a significant functioning factor in his school experiences, enriches both the child's relationship with his parents and with the school, fostering his adequacy and enhancing his security feelings.

Mental hygiene can be of service in helping to develop a sense of proportion regarding the seriousness of behavior disorders. Teachers still tend to overemphasize the seriousness of aggressive and hostile types of behavior. While not minimizing their disruptive effects upon the functioning of the classroom, more concern is needed regarding other types of behavior, such as marked timidity and asocial living, which while showing greater potentialities for emotional instability are not so forcibly thrust upon teacher consciousness.

Only within recent years has adequate rec-

ognition been given to the role that the teacher's personality plays in the success or failure of the educational program. Far more important than curriculum content, teaching methods, and the rest of the tangible aspects of the program designed to effect the end result of a well-balanced child, is the adequacy of the teacher's emotional adjustment. The well-adjusted teacher, with personal security and feelings of adequacy, is able to guide her pupils through their emotional weaning from home to their first adjustments to group living, to beginning awareness of abilities and limitations, and to authority. She is able to provide a classroom which is reasonably free from tensions, pressures, and rivalries. She can do this only if she is herself free from anxiety, is able to recognize and accept her own tendencies, and is aware of the extent to which teaching is satisfying her own needs. Then her own desire for achievement will not be carried out vicariously through the children in her class to such an extent that pressure is exerted for achievement, regardless of individual capacities. Dissatisfactions with her own life are not expressed in sarcasm, critical comments, inconsistencies in handling the children. Lack of adequate emotional or social satisfactions may result in the teacher's unwittingly satisfying her emotional needs through mothering the children, building up a relationship which will in effect retard their emotional growth. The teacher's rôle, except in rare situations, is not that of a parent substitute; rather is she the person who will help the child establish new, satisfying relationships with other adults on a friendly, comfortable, security-enhancing basis. She is aware that one of her functions is to lead the child out from the home patterns so that he can take his place adequately in the group, not to try to re-enact the home situation in the school. Teachers are at times hampered in the proper handling of behavior problems because they are not aware of their basis, incorrectly attributing their occurrence to their own teaching methods and handling. A safeguard against the development of anxiety about her own responsibility is the teacher's knowledge of behavior mechanisms and human relationships.

The teacher's need for adequacy, for success, and for a co-operative, comfortable relationship with her supervisors must not be

overlooked. In a period when there is considerable change in teaching techniques, the teacher is particularly subjected to pressures which may create conflicts about her adequacy, create insecurity feelings within her, and induce tensions which prevent her from functioning properly. She, too, has to be given consideration as an individual whose needs must be met if she is to provide the firm foundation upon which modern education is built.

METHODISTS, EDUCATIONAL ACTIVITIES OF THE. Methodism was born in a great university, Oxford, as the fulfillment of the dream of its scholarly founder,

METHODISTS, EDUCATIONAL ACTIVITIES OF THE

John Wesley. The educational policy of the American Methodist Church has been to provide necessary facilities for education, both institutional and otherwise. Final authority of the church in the educational field is vested in the General Conference, working through the Board of Education, which is organized in three major divisions, Division of the Local Church, Editorial Division, and Division of Educational Institutions. Any adequate description of the church's educational activities would include the organizational set-up through 105 annual conference and 40,000 local church boards of education, all of which must be omitted here. The normal educational machinery is intricate, but effective in its operation.

The first, and perhaps the most important, educational emphasis has been in the homes. This type of instruction seems to be the logical successor of the home school conducted by Susannah Wesley, the grandmother of Methodism, who religiously and systematically instructed her nineteen children. The next stage is now called religious education in the local church. It is not commonly known that the Sunday school, (the time-honored name), was launched by John Wesley even before the attempt credited to Robert Raikes, the generally recognized founder of the Sunday School movement.

Activities in the Local Church. The magnitude of the program in this field permits but a brief summary. In the 40,000 Methodist Sunday schools in the United States, 5,139,351, (1941 figures) persons are enrolled and taught by 502,427 volunteer workers. More than 1,200 schools for workers were conducted in 1942. Knowing the importance of parents as teachers of religion, these workers give large place to teaching future home makers. Increasing thousands of boys and girls attend week-day schools of religion, in connection with the public school year, and larger and growing numbers attend vacation church schools. The Methodist Church, with its ecumenical outlook, cooperates with other denominations, working in the International Council of Religious Education and other joint agencies by which it seeks to reach all races and nationalities.

Briefly stated, the church works toward the following goals through Christian education: (1) to foster a consciousness of God, (2) to develop an appreciation of Jesus and

his program for life, (3) to foster a continuous development of Christian character, (4) to develop persons into builders of a social order based on the fatherhood of God and the brotherhood of man, (5) to lead persons to become part of the church, (the organized society of Christians), (6) to produce an appreciation of and participation in the Christian family, the primary social group, (7) to lead growing persons to a Christian interpretation of life, seeing in it God's purpose and plan, with a philosophy of life built on this foundation, (8) to assimilate the best religious experience of the race, as undergirded in the Bible, leading to a satisfactory personal experience.

The Division of the Local Church is charged with responsibility in this field of activities. It is closely allied with the Editorial Division, which produces literature, periodicals and supplies needed for this service.

Institutional Education (The work of the Division of Educational Institutions.) The first venture in this field, Cokesbury College, located at Abingdon, Maryland, opened in 1787. The college operated with a fair degree of success until 1795, when the building was destroyed by fire. Upon confirmation of the news of the fire, Bishop Asbury expressed his conviction in the following sentence recorded in his journal, "The Lord called not Mr. Whitefield or Methodists to build colleges." Although the second Cokesbury, Baltimore, Maryland, burned in 1796 and the third Methodist college, the first chartered Methodist college in the world, Asbury in Baltimore, lived only a few years, the decades following the unfortunate endings of these first attempts do not afford evidence to substantiate Asbury's conclusion.

As in the field of erecting houses of worship, where the church followed, or sometimes almost preceded successive waves of pioneer population, so educational institutions were established within rather easy access to the church's constituency. The General Conference of 1824 voted to establish a college in every annual conference, declaring, "The church college is the bulwark of the church." This type of educational service was both important and generally successful for that day. Such activity, which ended with pioneer days, produced more institutions than were needed or could exist

MEXICO, EDUCATION IN

permanently. One historian says, "Randolph-Macon in Virginia, (1830), and Wesleyan, Connecticut, (1831), are considered the 'parent institutions' of the church." (Both are outstanding colleges now.)

The records of the Methodist Church list two hundred schools and colleges founded between 1835 and 1860. By the end of 1870, three hundred institutions had been established by the church, not more than one hundred of which still survive as Methodist. Educational activities in the church increased rapidly following the Civil War. Many colleges and universities, some of which continue to be among the best today, including Drew Theological Seminary, (now expanded into Drew University), 1867; Boston University, 1869; Syracuse University, 1870; Vanderbilt University (later becoming an independent institution), 1875; and others were established in this period. Important institutions have started since that post-war wave, but never in large numbers. In some cases progress was made by way of mergers and consolidations of institutions.

All branches of the Methodist Church have been active in their educational programs. Certain lines of work are mentioned here because they are characteristic of Methodists in general and, in essentially the same form, have survived both the strain of separation and the victory of unification. In 1866 a centenary educational fund totalling \$65,829.72 was raised. Of this \$56,674.40 was for the Children's Sunday School Fund and \$9,155.32 for the General Education Fund. Among the important by-products of this centennial observance were the establishment of the Board of Education, the starting of the Methodist Student Loan Fund, largely supported by Children's Day in the Methodist Episcopal Church, and the founding of the Freedmen's Aid Society. Since its beginning the Loan Fund has assisted more than 60,000 students through loans totalling over \$9,000,000. The Freedmen's Aid Society, and the successor board, have sponsored many strong institutions for Negroes, (14 at present), and various other educational activities.

The Board of Education, somewhat differently organized since the union of three branches of Methodism in 1939, continues earlier activities in addition to many new

features in the total educational program of the church.

Through the years the Methodist Church has operated or sponsored no fewer than 900 educational institutions of all types. Today there are 127 educational institutions related to the Board of Education of the Methodist Church, including 10 schools of theology, 9 universities, 67 senior colleges, 25 junior colleges, 11 secondary schools, and 5 of miscellaneous classification. These institutions represent an investment of more than \$400,000,000.

The educational activities of the church include a well organized Department of Student Work, the underlying philosophy of which is "the church follows its students." There are 110 Wesley Foundations, 100 organized student centers and over 200 other student groups through which the religious life of 200,000 Methodist students is given careful consideration to help them into the best possible experience of well rounded enlightened Christian character and living.

In addition to the above, current statistics indicate that the Board of Missions and Church Extension of the Methodist Church operates 360 schools in foreign lands and 37 in the United States. Included in the group are 8 universities, 35 colleges, 260 high schools and 93 professional schools.

The educational program of the Methodist Church is comprehensive and inclusive. It comprehends the entire academic field with as good institutions as are found in the world and the total sweep of religious and character education. It includes all who make up the constituency of the church, approximately 20,000,000. Not only does it include them all numerically, but it provides for adequate instruction and training in every area of their lives, from the cradle to the grave. H.W.M.

MEXICO, EDUCATION IN. The educational development of Mexico may be traced back to pre-Columbian times. The Aztecs had well-established centers of learning for both boys and girls. While these centers exercised an important influence upon Indian life prior to the Conquest, the coming of the Spaniards in 1519 brought about their complete destruction; modern education in Mexico reflects no direct response to those indigenous institutions. However, the cultural significance of the former existence of such

MEXICO, EDUCATION IN

schools is not to be overlooked, because the fact that the native peoples had attained this level of development has important implications for subsequent educational events during colonial days, in the nineteenth century, and, more particularly, during the twentieth century.

The founding of the first schools by the Spaniards immediately after the Conquest was a remarkable achievement in modern education. Fray Pedro de Gante, a Franciscan, opened a school at Texcoco for Indian children in 1523. Later, in 1526, he organized the great school of San José de Belén in Mexico City, also for Indians. The first institution of higher learning in the New World, El Colegio de Santa Cruz de Tlaltelolco near Mexico City, was founded in 1536 for Indian boys. The oldest institution of higher learning in the New World, now the preparatory school of the University of Michoacán at Morelia, *El Colegio de San Nicolás Hidalgo*, was founded by Bishop Vasco de Quiroga for both Indians and Spaniards in Pátzcuaro in 1540 as *El Colegio de San Nicolás Obispo*. The Royal and Pontifical University of Mexico, founded by the decree of 1551 and opened in 1553, has now become the Autonomous National University of Mexico. The old *Colegio de San Ildefonso*, organized out of several existing institutions around 1572, has become the National Preparatory School of the University of Mexico. In 1573, *El Colegio Mayor de Santa María de Todos Santos*, an endowed post-graduate and post-doctoral center of studies, was founded in Mexico City. This institution, like *El Colegio de San Juan de Letrán*, a school for *mestizos* which was founded in 1547, and several others of the sixteenth century schools, passed out of existence in the nineteenth century.

These schools, together with many others established in Mexico City and other parts of New Spain during the three centuries of the colony, constitute the foundations of Mexican education. The schools, largely church and church-state enterprises, passed through a golden age of development in the sixteenth century, becoming increasingly restricted in intellectual scope and outlook during the next two hundred years until, in the first half of the nineteenth century, they had become so formal and narrow that they fell into decay and most of them were closed. It was then

that Mexico, under the stimulus of recently acquired (1821) political independence, began to give serious consideration to state-supported public education. However, even though some schools were established and both legislation and public opinion favored extensive public education, the unsettled state of affairs that prevailed from 1821 until the expulsion of the French in 1867 prevented the organization of a system of schools.

In 1867, the National Preparatory School was founded on the ruins of the old *Colegio de San Ildefonso*, setting a pattern for secondary education which has spread throughout the nation. From 1867 on, both the state and national governments gave increasing attention to education. Vocational, normal, secondary, and higher schools were created in various parts of the nation and primary education became more widespread—the Federal government supporting activities in the Federal District and in the Territories; the state and municipal governments in their respective areas. These developments in the latter part of the nineteenth century and before 1910 were, nevertheless, inadequate to meet the needs of the nation and reached only a small, select sector of the population. In 1906 there were fewer than 800,000 students in all public and private schools in Mexico (less than 5 per cent of the nation's population) and 85 per cent of the people were illiterate.

The reestablishment, in 1910, of the National University, which had been suppressed in 1865, marks the beginning of a new interest in higher education and of new growth in centers of higher studies everywhere in the country. The Revolution, 1910-20, delayed this development but, since 1921, rapid strides have been taken at all levels. In 1929, the University became autonomous though its annual federal subsidy of \$3,000,000 (pesos), made through the Secretariat of Public Education, is still continued. The other universities are *Universidad de Michoacán*, Morelia, Michoacán; *Universidad de Yucatán*, Mérida, Yucatán; *Universidad Oficial de Guadalajara*, Guadalajara, Jalisco; *Universidad Autónoma de Guadalajara*, Guadalajara, Jalisco; *Universidad de Puebla*, Puebla, Puebla; *Universidad Socialista de Culiacán*, Culiacán, Sinaloa; *Universidad Obrera de México*, Coyoacán, D. F. In addi-

MEXICO, EDUCATION IN

tion to these schools there are numerous other centers of higher learning throughout the nation. The Secretariat of Education maintains a Polytechnic Institute in Mexico City. This school is made up of several vocational schools (grades 10-11), enrolling some 2,700 students, and six higher technical schools with more than 2,500 students. In 1939, the higher educational institutions granted 3,023 professional degrees, 56,595 such degrees having been granted since 1901.

The Secretariat of Education operates 26 rural normal schools (4 of a higher elementary and 22 of a secondary level) which enroll 3,263 students. The National School for Teachers in Mexico City, under the Secretariat of Education, is a post-secondary school enrolling 1,234 pupils. In addition, state-supported normal schools are found in virtually every state capital and large center of population in the nation.

Since its establishment in 1921, the Secretariat of Public Education has gradually taken over most of the burden in elementary and secondary education in the nation. Public schools of eleven states (and of the Federal District and the three Territories) have been federalized and, in the other seventeen, the national government operates many schools alongside those supported and administered by the states. The national government, through its several departments but principally through the Secretariat of Education, spends more than \$90 million (pesos) annually for education; the states and territories more than \$45 million (pesos). The budget of the Secretariat of Education in 1941-42 was \$77,850,000.00, or 15.79 per cent of the total federal budget.

Elementary education (*escuelas primarias*) in Mexico covers grades 1-6, inclusive; secondary education (*escuelas secundarias* or *de segunda enseñanza*), covers grades 7-9, inclusive; and vocational and college-preparatory education, offered in the *escuelas vocacionales* and *escuelas preparatorias*, respectively, covers grades 10 and 11. The national government supports 13,358 primary schools; the states and municipalities, 7,420. In addition, 977 are maintained by state-federal support, 991 by industries in compliance with federal law, and 445 are operated through private initiative. These schools are taught by 46,653 teachers and enroll 2,037,870

pupils. Most of these schools have night classes for adults and, in addition, there are 91 federal schools for adults with 488 teachers and an enrollment of 8,760. Some thirty-five residential schools for Indians are maintained by the Federal Department of Indian Affairs.

The Federal government maintains 251 *escuelas secundarias* (with either pre-vocational, vocational, academic, or agricultural curricula at 7-9 grade level) with an enrollment of 43,984. There are no recent figures on either vocational or preparatory (grades 10-11) schools. It can be estimated that the enrollment in the former is less than 25,000 while, in the latter, the enrollment is probably in the neighborhood of 15,000. Schools of this level are found in various parts of the country—in connection with higher schools, as private schools, or supported as common schools by the states or by the Federal government. Their number is increasing rapidly.

Since 1921, the schools of Mexico have been characterized by realism and by a social philosophy of education. Rural education and the education of Indians have been pointed to the solution of the immediate, vital problems of the common people—health, subsistence agriculture, literacy, national and indigenous languages, and the like. Primary and normal schools everywhere are giving increasing attention to current social and economic problems as well as to Mexican culture. Much of secondary education emphasizes vocational preparation. The universities and other centers of higher study, though still emphasizing literary curricula, are rapidly developing scientific laboratories and technological programs. In all of these developments can be seen the expression of the two dominant, traditional tendencies of Mexican educational endeavor: the academic, humanistic, and theoretical education inherited from the Renaissance; and the realistic education inaugurated by such sixteenth century educators as Fray Pedro de Gante and Bishop Vasco de Quiroga, carried out in higher schools to a limited degree by the Jesuits, revived to some extent in the educational reforms of the nineteenth century, and given primary stress in the educational awakening resulting from the Revolution of 1910-20. These two tendencies, if properly correlated, give promise of evolving into a

highly attractive program of balanced intellectual and cultural development in Mexico.

MILITARY EDUCATION. In the United States, the official training of our citizens in military skills for military purposes has not been an integral part of national practice. The idea that wars could be fought by farmers and tradesmen who took their muskets from the pegs over the mantelpiece and marched forth to defend their homes under command of the local merchants and lawyers has tended to be the American ideal of military education precisely because the traditional American theory of the perfect state has not allowed for a large standing army. Americans have entered upon their wars depending for the mass of their forces on their citizen army, civilians trained and equipped after war has been declared. However, such theory and practice have seldom survived without modification a critical period of large-scale conflict with other nations. World War I brought changes. World War II may shift our ideas of military education to a new center of gravity.

The complexities of modern warfare make the farmer-into-soldier ideal impractical, and require that the soldier be a specialist, but the basic theory of a citizen army is part of the fabric of American thought and is embodied by the War Department of the Federal Government in its published Army Regulations.

The Citizen as a Soldier. With America's entrance into the Second World War, December 8, 1941, theoretical considerations were cast aside and the Government, largely supported by public opinion, set about to

create an armed force adequate to a conflict which involved whole populations and ranged over the whole land, water, and air surface of the earth. This called for a program of education, the largest and most complex of its kind ever undertaken in America.

The framework for this training program had been provided by legislation passed by Congress during and after World War I. The National Defense Act of 1916, as amended in 1920, authorized a broad program of civilian military training, to run parallel to the concentrated training provided by the Regular Army for its members, instruction to be given by Regular Army officers, and the whole system to be under the jurisdiction of the War Department. The Act was designed to provide some military training for a part of the civilian population, with the object of creating a reserve of trained officers and men to assist with mobilization of man power in time of war.

Because national interest in military training is naturally stimulated by war, legislation for military training has closely followed the first years of our chief military conflicts. The Morrill Act of 1862, when it authorized grants of land and Federal aid to establish colleges for agriculture and the mechanical arts, specified that military drill should be included in the curricula. The Act of 1920 provided for the establishment of a Reserve Officers' Training Corps unit in every land-grant college, and in any other educational institution of college or secondary school level which would insure the enrollment in such a unit of not less than 100 members. An officer of the Regular Army was to be assigned to each unit as Professor of Military Science and Tactics. The Federal Government was to provide arms and equipment to be used for purposes of instruction.

This Act has served adequately as originally envisioned. The course consists of three hours of instruction and practice a week in basic citizenship and the fundamentals of military discipline and drill. If the student desires to continue his training, there is an advanced course, two years of approximately five hours a week. Upon completion of this advanced course, and with an additional six weeks' training at a summer camp course, the student may receive a commission in the Officers' Reserve Corps, from which he will, in

MILITARY EDUCATION

time of war, be absorbed into the Army of the United States.

At first most of the ROTC units were infantry, cavalry, or artillery, but gradually some schools added signal and air corps units as well, and the establishment of medical, dental, and veterinary corps units was authorized by Acts of Congress of 1919, 1920, and 1924. The National Defense Act also authorized the establishment of Citizens' Military Training Camps to provide short summer training courses for non-college students.

Another organization which provides auxiliary military strength is the National Guard, which is supported jointly by the Federal Government and the several states. Citizens belonging to the National Guard receive approximately 90 hours a year of military training in Armory drill and field exercises, plus many correspondence course hours. The National Guard of each state as a whole is subject to call by the Governor in case of riot or insurrection within the state.

All these auxiliary military organizations are subject to call to active duty by the President. In time of war they combine with the Regular Army to form the Army of the United States.

In peacetime the instructors for all these organizations are officers of the Regular Army. In wartime, or during periods of emergency, these are replaced in part by Reserve officers.

In the two decades after World War I, there was in the United States widespread popular revulsion against military training. Public opinion was affected by the controversies that arose over the status of the ROTC courses in various colleges and universities. The law, as generally interpreted, made two years of military training compulsory for the students. In practice, "drill" frequently took the place of what was then generally considered a well-rounded program of physical education, and, in so far as "drill" did not provide a balanced program, there was a legitimate cause for the disapproval of educators and public. The controversy continued to grow. The whole premise underlying the military training of civilians was called into question by some teachers and their followers. The ideals and methods of the Department of Military Science and Tactics were believed by

a vociferous group to be inconsistent with the liberal humanist aims of higher education. [The Supreme Court of the United States, in passing upon the constitutionality of compulsory military training in colleges and universities, under the provisions of the Land Grant Act, decided that such military training was a proper requirement and could be enforced by the university authorities. (*Coale v. Pearson*, 290 U.S. 597; *Hamilton et al. v. Regents of the University of California*, 293 U.S. 245, 1934.)] Greater attention by the War Department to the course of study brought about many improvements in both the interest and value of the instruction given. The "compulsory" status of the law was challenged by several universities, and removal of this clause, by amendment in 1936, eliminated much of the basis for argument. In spite of some opposition in academic circles, the ROTC units continued to turn out an average of 6,000 graduates a year, who were granted commissions in the Officers' Reserve Corps, and who, at the time of the Second World War, were almost immediately absorbed into the Army of the United States.

Military Education within the Armed Forces. In time of peace the Army has its own task to do—great programs of civil engineering and mass sanitation, and important investigations and projects concerned with the raising and maintaining of standards of health and convenience of intercourse within the nation as a whole. Members of the Regular Army, in addition to being soldiers, are specialists in many fields. They may be engineers and lawyers, research scientists and doctors; they may be experts in supply or transportation, or specialists in finance or personnel management. Thus, it is obvious that the Army must maintain a comprehensive system of education within its own ranks. It must be a flexible system, in which training for specifically peacetime objectives may be quickly converted to military purposes in time of war.

The naval branch of the military system has its peacetime jobs as well, in assisting international communication and trade, adding to the scientific and practical knowledge of navigation, and protecting and policing the outlying possessions and territories of the United States. The Navy, in order to carry out its program, conducts schools and train-

MILITARY EDUCATION

ing courses for its personnel, always with a view to supplying the type of training which will best equip this fighting branch for the rôle it may be called upon to play under peacetime conditions and during hostilities.

The primary sources of trained officers for the regular peacetime Army and Navy are the two great academies the United States Military Academy at West Point, New York; and the United States Naval Academy at Annapolis, Maryland. The prestige of the American academies is as great as that of any comparable institutions in the world. Students come from all walks of life, and appointments are made on a geographical basis of popular representation of the whole nation.

The course of study at West Point is the same for all students, and emphasizes, outside of the regular tactical and allied military subjects, mathematics and modern languages. Annapolis stresses languages even more than does West Point. Both schools provide constant instruction in the actual practices and techniques of military and naval warfare.

Upon entrance to these two schools, the students become charges of the Federal Government, under the aegis of the War Department and the Navy Department; and must agree to serve, in the case of the Army, for four years after graduation; in the Navy, for two. Academic and physical standards, both for entrance and for graduation are high; the students are at all times under strict military discipline; and the traditional attitude of the graduates is one of service for loyalty to the Federal Government. Graduates of West Point are commissioned as Second Lieutenants in the Army; those of Annapolis, as Ensigns in the Navy.

Secondary sources of officer-material are the old-line military colleges, such as The Citadel in South Carolina, The Virginia Military Institute, and Norwich University in Vermont. These schools are not under the jurisdiction of the War Department. Their graduates, therefore, do not go automatically into the armed service; they have, however, active departments of military education; and they provide a steady stream of officers for the Officers' Reserve Corps, for the National Guards, and in some cases for the Regular Army. The university and college system, especially in land-grant colleges and universities, has been another major second-

ary source of such officer material, one of the most important of which has been the Agricultural and Mechanical College of Texas at College Station, Texas. In fact, it may even be said that in time of war the university and college system becomes the primary source of trained officers for the armed forces of the country, except in so far as providing general and flag officers is concerned. Throughout the nation's history a tertiary source of material has been such essentially military academies as Culver, Staunton, Wentworth, San Diego Army and Navy, and New Mexico Military Institute.

The other major unit of the armed forces of the United States is the Marine Corps which serves as a collateral branch of both the Army and the Navy, although its loyalties and traditions are more closely connected with the Navy than with the Army. Technically, a marine is a "sea soldier" and from the earliest times when the early colonists were of necessity a sea-going people, the marines were organized for both land and water operations. Combat versatility and initiative have distinguished the Marine Corps ever since. As such, the Marine Corps has frequently been an agent of the Department of State. In addition, it has served as a police force, or as a colonial army, for all American possessions and spheres of influence. Many Marine officers are trained at Annapolis and by virtue of the close alliance with the Navy and the nature of their combat operations the two services must be integrated and inter-staffed to a high degree. On the other hand, in most major conflicts Marine regiments have served with the Army. Consequently, their training program somewhat parallels that of the Army, and Reserve officers for the Corps are trained in part through ROTC units maintained by colleges and universities. As in the case of the Army and Navy, once in the service, Marine officers and enlisted men attend special service schools at such places as Quantico, Virginia; and New River, North Carolina.

Men who join the United States Army, either as officers or as enlisted men, are apt to find that however much education they have had before, a new school career has only just begun. For example, a young officer who has been commissioned in the Infantry or Field Artillery will be assigned to duty with

MILITARY EDUCATION

his regiment, or separate battalion, and in normal times will spend from two to five years at an Army station, assisting in the training of enlisted men, or fulfilling other general duties assigned to him by his commanding officer. Then he may go, for review and advanced study, to the special service school of his own branch, such as the Infantry School at Fort Benning, Georgia. Next, if his record and capacities warrant it, he may be detailed to attend one of the General Service Schools, such as the Command and General Staff School, at Fort Leavenworth, Kansas, where the course of study aims at training officers in command and general staff duty, and in the integration and coordination necessary to make all branches of the armed forces act together effectively. Then, after a peacetime service of seventeen or more years, the officer, having achieved the grade of major or lieutenant colonel, may be appointed Professor of Military Science and Tactics, in charge of an ROTC unit at some university; ordered on a tour as instructor with National Guard units anywhere in the country; detailed to the Army War College or Army Industrial College for higher command or staff postgraduate work; or quite possibly he may serve with troops or other Regular Army installations in a command or staff capacity. In time of war both the Special Service Schools and the Command and General Staff School provide refresher courses.

The enlisted man in the modern army must also be a specialist. Under the procedure adopted in World War II, after a three-month basic training period at a Replacement Training Center, the new private, on the basis of intelligence and aptitude tests, with additional classification data as to his personal background and civilian experience, may be assigned to a special service school, of which there is one for every branch, new and old, of the armed service. He may be sent to the Field Artillery School or to the Radio Communications branch of the Signal Corps School; or if he has had, for example, civilian experience in personnel management or machine record work, he may be sent to The Adjutant General's School for special courses, or to take an Officer Candidate course, upon completion of which he may be granted a temporary commission in the Army of the United States. Some of these special service

schools were an outgrowth of the changes in methods of warfare since World War I and were established to create units properly trained for the tempo of World War II. Still another class developed by the tempo of World War II was the short orientation-type courses which were conducted by some arms and services such as The Inspector General's Orientation School at Washington, D. C.

Not unlike the training program for the Army, the training program for Naval personnel who have been two years at sea has provided additional officer training for selected personnel, such as those programs found at the Submarine School or the Torpedo School. Following a period of six or seven years' sea duty, officers become eligible for such postgraduate instruction at the United States Naval Academy as the line course, naval radio, ordnance, aeronautics, naval architecture, or mechanical engineering instruction. Such courses have been supplemented frequently by detailing officers directly to specialized courses in engineering, ordnance, fire control, metallurgy, explosives, torpedo design, naval construction, or civil engineering at such civilian technical colleges or universities as Massachusetts Institute of Technology, Carnegie Technical Institute, California Institute of Technology, Rensselaer Polytechnic Institute, and Harvard or George Washington Universities, the University of Michigan, and Babson Institute. As in the case of the Army, the Navy has provided for postgraduate work, the Naval War College being located at Newport, Rhode Island. World War II greatly augmented the number and types of schools available and eliminated, at least temporarily, many of the normal officer details for further technical training, which may be said to be the order of expectancy during peacetime training procedures. Training of enlisted personnel, ashore and afloat, has been provided by the Navy through its Bureau of Navigation or by programs sponsored by the Chief of Naval Operations. Ashore, the training of Naval enlisted personnel has been grouped under three classes of service schools with complete training programs at various points, such as San Diego, California; Norfolk, Virginia; Great Lakes, Illinois; Washington, D. C.; Lakehurst, New Jersey; and Pensacola, Florida.

MILITARY EDUCATION

Other types of schools have been maintained and administered aboard ships of the fleet.

Training for Modern War. The need for increased mobility has been recognized, the lessons of battles on all fronts are absorbed, and the Army has been "streamlined for action." The tempo of World War II created an immediate action situation which has been recognized by all the armed forces, as indicated by extensive and intensive training schedules. For example, primary attention has been given by the Army to the military education of the personnel of the Army Air Forces through their many special training command schools, including flying training command schools, technical training command schools, and the school of aviation medicine. In general, these schools provide trained personnel for manning military aircraft, including pilots, glider pilots, bombardiers, navigators, observers, and aerial gunners. In great numbers, parachute troops and commandos have been trained, the latter in both the Army and the Marine Corps. In addition, comprehensive training has been given to those inducted into the Army at Induction Stations and sent to Replacement Training Centers so as to insure that the men were assigned to those units for which their previous skill or knowledge best fitted them; in addition, as a result of this course, those who demonstrated unusual abilities and aptitudes have been selected for further training at Officer Candidate Schools for possible commissioning as future leaders.

A great deal of emphasis in modern military education has been placed on the use of training films. They have been found to be an excellent medium for training large groups of men in limited periods of time.

Under World War II policies, civilian facilities have been used wherever their use would save time and construction and accomplish the same training objective. Approximately 400 such civilian schools, including factory schools, trade schools, colleges, and universities, have been used to give instruction to military personnel. All matters pertaining to their use have been coordinated through the appropriate staff agency which has prescribed major policies such as the character, length, location, content, and texts of the course. Civilian schools have also been leased for dormitories, mess facilities, class-

rooms, offices, and drill fields. The Army has furnished the training aids and instruction. This has been done at Harvard for the Chaplains, Princeton for Army Exchanges, and Duke University for Finance. Surveys were made constantly to determine available school facilities. Once the training programs got under way, a constant check was maintained to insure the proper fulfillment of all training objectives.

Likewise, in time of war, all sources of man power must be integrated under the exigencies of total war conditions, including the education attainments of all trained persons who virtually serve as a reservoir of strength upon which to draw wherever and whenever circumstances require their use. This has been accomplished in part by temporarily commissioning eligible specialists with or without previous commissioned service in the Army of the United States.

As in other periods of American history, women appropriately trained and organized have participated; the organization of the WACS and WAVES [Women's Army Corps and Women Accepted for Volunteer Emergency Service (Women's Reserve of the United States Naval Reserve)] are typical of the auxiliaries which have released men for combat duty.

In time of war, therefore, the armed forces need and get the services of innumerable types of men and women for a wide diversity of jobs. Public opinion in America has shown itself to be in favor of this. How much change World War II has made in our basic national attitude toward military education as an instrument of national policy is yet to be determined. The change may be profound.

Despite some critical evaluation of the progress which has been made in the large-scale training programs in all branches of the Armed Forces, it may be said that a scrutinizing impartial evaluation of the total training program evolved by World War II has shown tremendous strides toward satisfactory training, under conditions fraught with difficulties despite the cooperative public attitude and a military leadership which recognizes the imminent necessity of putting that virile declaration of Theodore Roosevelt into action: "Cut the chat and dig the ditch!" In brief, then, the military education and training of the American soldier, sailor, and

MILK SERVICE IN PUBLIC SCHOOLS — MINIMUM ESSENTIALS

marine during this period have continued to receive the constant attention of those charged with the responsibility of welding into shape an efficient and victorious fighting force—a force fully cognizant of its rôle in the struggle of civilization to maintain itself. G.F.M.

MILK SERVICE IN PUBLIC SCHOOLS.

Many elementary schools provide milk for the children enrolled. The primary objective in serving milk is to improve the health of undernourished children. However, the milk may be supplied to children other than the undernourished.

The milk is usually served in the morning about midway between breakfast and the luncheon period.

Practice in supplying the milk varies widely in the different schools. In some schools the children purchase their own milk. In other schools milk is furnished without charge to those pupils needing milk, but who are unable to pay for it themselves. O.G.J.

MINIMUM ESSENTIALS. The original "minimum essentials" in education were considered to be the 3 R's—reading, writing, and arithmetic. As schools developed and knowledge expanded, additions were made to the curriculum without much thought of a fundamental reorganization.

The movement to determine minimum essentials grew out of curriculum thinking in the early 1900's in order to bring about reorganization and simplification of a curriculum which had developed by the accre-

tion of new subjects and new subject matter.

In the preface to *How to Organize the Curriculum* (1923), Charles A. McMurry says:

"The elementary curriculum has expanded in recent years into a huge collection of knowledge and of activities. Nearly all the subjects suitable for children and some others have been gathered from all sources until both teachers and children are overloaded with these bountiful gifts. At present they are staggering under the load.

"The last thirty years has been a period of almost reckless expansion of common-school studies into all the new and old realms of experience. It may require the next thirty years to sift out and to organize these accumulated treasures.

"Our problem is that of selecting and combining the best and most essential influences into a simple program which will promote the continuous educative growth of children through the school period."

Responding to this general feeling, educators attempted to determine the minimum essentials. This did not call for a reorganization of subject matter but rather for a selection of those items that seemed to be most necessary and essential. As a result, minimum essentials were selected in practically every subject field—especially in the tool subjects such as spelling and arithmetic. Efforts were made also in a number of courses of study to interpret minimum essentials in terms of understandings.

The approach to curriculum reorientation through the elimination of nonessentials, however, did not materialize into an effective movement. This was due, in part, to conservative influences, which kept old subject-matter programs intact and resisted the development of newer materials. Likewise, fundamental curriculum orientation could not be achieved merely by the lopping off of topics and the pruning of subjects. McMurry further criticized the movement as follows:

"This quantitative reduction of subject matter in studies to minimum essentials has also a powerful tendency to end rather in a collection of dry abstractions, and these properly joined together furnish us with the 'grinning skeleton' of a course of study...."

The minimum essentials movement gave little consideration to a fundamental consideration of curriculum aims, purposes, and directions. The factors involved in attempting to think through this problem are indicated in a statement from the *Fourteenth Yearbook* of the National Society for the Study of Education:

"If it is impossible to discover from educational theory fundamental tests for exclusion and inclusion, we are driven to the method of determining

MIXED RELATIONS TEST — MODERN FOREIGN LANGUAGE "STUDY"

minimum essentials on the basis of the best current practice and experimentation which give satisfactory results. Those results are satisfactory which meet adequately the common needs of society. This in the main is the method employed in the investigations upon which the following reports in the yearbook are based."

An outstanding example of an effort to organize a course of study on the basis of minimum essentials is that developed by a Committee of Superintendents in the State of California under the direction of Ernest C. Moore. The Committee approached its problem by asking, among other things, these questions:

"What parts of it (your subject) are of first-rate importance, as distinguished from the parts of it which are only of second-rate or third-rate value? What are its essentials? We ask you to skeletonize it, to outline its minimum essentials."

The result of the work of this committee was a sizable volume which, for the most part, outlined subject-matter content. On the other hand, some recognition was given to other values since, in the section on geography, it is stated: "It is not facts, but system of facts, which constitute minimum essentials in geography."

Many courses of study included a statement of minimum essentials during the period 1920-30. Since 1930, however, the term has not been in general use. Dr. William C. Bagley headed a group known as "The Essentialist Committee for the Advancement of American Education." Dr. Bagley's protest was against what he considered to be "the disparagement of system and sequence in learning and a dogmatic denial of any value in, even of any possibility of learning through, the logical, chronological, and causal relationships of learning materials." A consideration of the view presented by Dr. Bagley indicates that his concern is primarily, however, for "the need of common elements in the basic cultures of all people especially in a democracy." The point of view expressed by the essentialist is much broader than that proposed by the original minimum-essential group, and in a measure serves to indicate a change in thinking as to what is considered essential. Any canvass of the field reveals a broadening concept of the curriculum. It is more generally recognized that the aims of education can be achieved through many types of materials and activities.

The term minimum essentials has been re-

placed largely by "functional subject matter," wherein an effort is made to develop educational experiences which will assist the individual in the control of his environment and, at the same time, insure the knowledge, skills, attitudes, and appreciations for creative living.

MNEMONIC DEVICES. Mnemonics refer to any device or system for assisting or improving the memory (*q.v.*). Thus, the names of the Great Lakes are more easily recalled by the pupil who remembers that their initials spell the word *homes* (Huron, Ontario, Michigan, Erie, Superior). Devices are sometimes sanctioned when the material is factual and without possibilities for association, as when the teacher tries to get children to remember the correct spelling of *hear* and *here* by thinking of *hear*—ear and *here*—there. Psychologists, however, hold that mnemonic devices are not so effective as are understanding, meaningful associations, the will to remember, and spaced recall. Devices are only crutches which should be used sparingly, and then only in cases of artificial and arbitrary items. As curricular materials become more meaningful and significant to children, there is diminishing emphasis on artificial mnemonic devices.

MODEL LESSON—See DEMONSTRATION TEACHING.

MODERN FOREIGN LANGUAGE "STUDY." The wave of influence of the "direct method" (*q.v.*) in the first two decades of the 20th century, combined with the conflicting experiences of World War I regarding the foreign language skills of our soldiers,

MODERN FOREIGN LANGUAGES, TEACHING OF

began to raise serious doubt among foreign-language educators as to the efficiency of existing teaching methods in this field. Consequently the American Council on Education was requested to organize a fact-finding investigation into the status of the teaching of modern foreign languages. In 1924, taking the name *The American and Canadian Committee on Modern Languages*, a large committee was formed to cover the United States and Canada. Subcommittees were set up in every region in the country and operating funds were obtained from the Carnegie Corporation of New York. Coleman² wrote the basic volume of the whole investigation, interpreting the data from thousands of questionnaires and from the extensive survey of student abilities by tests, setting up lists of valid objectives, and making recommendations for future curricula. There were, in addition, twelve volumes of reports on teacher training, enrollments, achievement and prognostic testing, and reading skill; and six volumes of frequency word and idiom counts for French, German, and Spanish.

The standardized tests created by the "study" have been used by hundreds of school systems and are still valid. The frequency counts have affected, especially at elementary levels, most of the textbooks produced since their appearance. Most important was the recommendation, although not unanimously endorsed, that the short two-year course—which, it was found, was the term of study of fully 83 per cent of high school registrants—emphasize the skill of reading for comprehension, with all others skills made ancillary to this central aim. In spite of spirited debates on the part of proponents of the oral approach, the reading aim has been adopted widely by state and city syllabi and courses of study. Both foreign language authorities^{4,5} and educators¹ have endorsed the aim as the most likely solution to foreign language curricular problems. The work of the "study" is being continued by the Committee on Modern Languages of the American Council on Education, which has expanded its activities to include consideration of problems in the teaching of English as a foreign language, continuation of the work of the study in preparing bibliographies of modern language teaching, continuation of the work on standardized tests, and the mak-

ing of syntax frequency counts in the major foreign languages.

MODERN FOREIGN LANGUAGES, TEACHING OF. In earlier times languages were "picked up" by mouth-to-ear tutorial means, even when the oral use of Latin as an almost universal auxiliary language gave the name Latin Quarter to a section of Paris inhabited by students from all quarters of the globe. Since then the grammarians have coded the rules and a grammar-translation approach to learning the classical languages transferred its deadening yoke on to the modern languages as they began to be more and more widely studied, first in colleges, then in schools.

The first "reform" came in Germany in 1880 when Viëtor issued his pronunciamento that language teaching should about-face from grammatical technicalities to a living approach, with phonetic treatment of pronunciation. The pendulum swung to the Natural Method, espoused by Dr. Sauveur in the U. S. There was the Ollendorf method of question-answer (but via translation from the mother tongue following grammar study) and the Gouin "series" method of organized sequences of actions (such as verb-study by the step-by-step actions of entering a room through a door). The Direct Method (*q.v.*) could be called a schoolroom adaptation of various features of these methods, with emphasis on direct comprehension of vocabulary in oral language, with inductive learning of grammar and phonetic help in pronunciation.¹

The Report of the Committee of Twelve⁷ of the Modern Language Association of America in 1898 described and evaluated the existing methods in secondary schools but in general accepted the four-fold aim of giving somewhat equal stress on speaking, writing, aural

MODERN FOREIGN LANGUAGES, TEACHING OF

understanding and reading. Reading was recognized as the skill that would bring the greatest good to the greatest number, but it was identified with translation into English of literary texts.

The *Modern Language Study* of 1924-28 (q.v.) and its related agencies broke another lance on the ever-continuing grammar-translation system which could, however, always claim solid work done, especially in colleges and private schools. The conservatism of the foreign language examinations of the College Entrance Examination Board (q.v.) tended to keep the grammar approach alive. The wide prevalence of the two-year course in smaller school systems, along with the evidence from test campaigns and questionnaire returns from teachers that present methods were not producing satisfactory results, caused the *Study* to recommend a "reading" approach to these shorter courses.

The reading approach was not entirely approved, especially by proponents of oral approaches such as de Sauzé with his "Cleveland Plan" and Mercier with his "Oral Self-Expression" method, who claimed that not all the evidence was in. Reading programs were already in existence, especially that at the University of Chicago, organized by Hagboldt (German) and Bond (Romance), and that devised by West in India (English).⁹ At the high school level Helen M. Eddy (University of Iowa High School) published a learning system in French and L. A. Wilkins (New York City Schools) prepared materials in Spanish, adapting the West techniques to American schools. The oral approach, however, is by no means dead, and World War II brought into prominence the language teaching in Japan by two exponents of an oral approach: Palmer⁵ for English and Marchand for French. The wide acceptance of the "Good Neighbor" attitude with our southern neighbors has given a renewed impulse to the study of Spanish and a start to Portuguese and the first rush is to acquire oral skills.

Meanwhile other curriculum forces have been operating to confuse the situation. The academic demands of college entrance requirements are disappearing as almost every college and university abandons the requirements of entrance credits in a foreign language and as nearly all but the liberal arts colleges abandon the foreign language re-

quirement for graduation. That students may succeed in college without definite, prescribed knowledges and skills appears amply proved by the reports of the *Eight-Year Study* of the Progressive Education Association (q.v.). Foreign languages are now almost entirely elective and the general language course (q.v.) is becoming increasingly effective as a preliminary orientation to some pupils and as a language arts substitute to others. It may be said of methods in summary that successful oral approach systems exist largely in city school systems, some colleges, and some private schools; reading approaches are more prevalent in smaller schools; and the grammar approach still persists in any kind of system. There are, however, many exceptions to this statement.

Numerous forces have operated in recent years to bring a gradual decline in the study of foreign languages. New courses entered the secondary-school curriculum as it attempted more and more to provide in a democratic way for the differing needs of boys and girls. Rarely was a course dropped when a new one came in, and big high schools (strongly aped by smaller ones) tried to use the college plans of laying down an "academic" sequence of courses, a "vocational" sequence, etc. The new experimentation with contract plans, broad-fields (q.v.) courses, fused curricula, and especially the "core-course" (q.v.), has tried to merge subject areas and break down barriers. These plans have been of little help to foreign languages, which do not seem able to "merge" well, do not adjust to the "core", and strongly resent even the idea of "general" language. There is keen competition among the different languages for pupil time, while enrollment destinies rise and fall with political events and with curricular experimentation and administration.

Purin⁶ tabulated for the *Study* the questionnaire returns on teacher training. Although hundreds of very well trained teachers were revealed in the country, in the main a large percentage were poorly prepared, especially in the oral skills, revealing one strong reason why results have been poor. A recent study among French teachers may be considered representative.⁴ In most regions more than half of the teachers had the M.A. degree and

MODERN FOREIGN LANGUAGES, TEACHING OF

many had lived or traveled in France. In senior high schools and colleges the teachers averaged 10 to 15 years of experience and the memberships in professional societies were creditable (although too few).

In the three statistical tables below are

given enrollment figures.⁸ It may be seen in Table I that the highest percentage was in 1915, although it must be understood that the great increase of school populations has brought more actual *pupils* into language classes recently than in previous years.

I. Percentages of High School Populations Studying Foreign Languages

Year	1890	1895	1900	1905	1910	1915	1922	1928	1934
Latin	34.7	44.0	50.6	50.2	49.0	37.8	27.5	22.0	16.0
All Mod. Languages .	16.4	17.9	22.1	29.4	34.3	35.6	27.4	25.4	19.7

II. (a) Percentages of Total Number of French Students Enrolled in Their First Year of Study, Distributed as to Grades

Grades	7	8	9	10	11	12	7-9	10-12
Public Secondary	3.7	9.3	28.9	30.9	24.3	2.9	21.9	78.1
Private Secondary	10.0	12.7	29.8	27.1	17.8	2.6	52.5	47.5

(b) Percentages of Total Number of French Students, Distributed as Enrolled in Their 1st, 2nd, 3d and 4th Years of Study

Year of Study	1	2	3	4	1-2	3-4	5th
Public Secondary	55.5	32.0	11.0	1.5	87.5	12.5	
Private Secondary	48.5	29.7	15.8	5.9	78.2	21.7	0.1

III. Shifts in Distribution of the Foreign Language Enrollment in New York City Senior High Schools During 23 years

Year	French	Ger- man	Span- ish	Italian	Latin	Ratio to School Population
1917	23.2	27.1	0.1	25.3	24.3	103
1920	30.7	0.1	0.2	45.6	23.4	90
1925	35.8	5.9	1.2	29.3	27.8	81
1936	45.5	10.6	5.1	24.3	14.5	61*
1940	43.7	8.0	7.2	35.6	13.8	57*

* In 1936 there were 1,539 students of Hebrew; in 1940 there were 2,714, 1.7% of the enrollment.

In Table II the figures show how study was concentrated in the 9th-11th grades (note the small enrollments in 7th-8th grades) and how the great number of pupils study foreign languages for only two years. Table III shows the ups and down in language enrollments in a large city as wars come and go. Happily German has not dropped to nothing in the second World War as it did in the first; note the steady decrease in Latin. The very recent increases in Spanish are known only for the colleges through the data in *Crofts Modern Language News* of Nov., 1941, based on reports from 526 institutions: French was down 23.5 per cent from the year before, German down 11.0 per cent, Spanish was up 27.0 per cent. In 1940 French was down 15.5 per cent, German down 3.3 per cent, Spanish up 21.5 per cent over 1939 figures. In Nov. 1942, based on reports from 509 colleges, French

was down 23.7 per cent from the autumn of 1941; German down 11.6 per cent; Spanish down 1.0 per cent, doubtless due to wartime withdrawals into service or production.

Although vocational values are claimed for a very few learners and strong stress has been put on cultural values (knowledge of the people, customs, etc.), the study of foreign languages must yield values in skills and understandings and appreciations. Many variations can be cited of school aims as they have been framed for current teaching. The following statement has been endorsed by most of the outstanding foreign language educators of the country; it may be considered typical of a suggested syllabus for secondary-school courses.

The Aims of Modern Language Instruction. The aims of courses in modern foreign languages will have to depend on several factors: the preparation of the teacher, the teaching situation, the materials available, and certain administrative factors, not the least important of which is the amount of time at the disposal of the teacher. The statement proposed as a frame of reference for tentative high school syllabi now in preparation by the Ohio Council on Modern Language Teaching, lists the following aims as best suited to the minimum course in a modern foreign language:

I. To develop an ever-increasing ability to

MONISM

read for recreative and vocational purposes materials in the foreign language, beginning with graded reading texts and progressing to books, newspapers, and magazines within the scope of the student's interests.

II. To aid the student to acquire such knowledge of the grammar of the language as is demonstrated to be necessary for reading with comprehension and speaking with relative grammatical accuracy.

III. To aid the student to acquire relative accuracy in pronunciation, and to achieve the ability to understand and to use the language within the limits of his vocabulary.

IV. To provide for an ever-expanding student knowledge of the foreign country (or countries) whose language is being studied, its history, institutions, ideals, and contributions to our civilization, and the life and characteristics of the foreign people in order that students may have a less provincial attitude towards the merits and achievements of other peoples.

V. To provide for an increasing knowledge of the meanings of English words through a knowledge of the foreign words from which they have been derived, and for an increased knowledge of the principles of English grammar, and of the relationships between the foreign language and English. (See DIRECT METHOD OF TEACHING FOREIGN LANGUAGES; MODERN FOREIGN LANGUAGE "STUDY".)

MONISM. All philosophy may be said to be monistic, that is, single, in the general sense that it directs attention not only to the totality of experience but also to a harmony, consistency, or unity of its individual and conflicting items. Ordinarily and more specifically monism is a theory that the nature of reality can ultimately be reduced to a single principle. What that single principle is, however, is a moot point. Those who reduce everything to matter or physical energy are usually known as materialistic monists, while those who reduce all to mind or spirit are called idealistic monists.

Materialistic monism is to be found at a number of points in educational thought and practice. It is most notable in the field of educational psychology. Here the tendency of scientific psychology has been to reduce psychological phenomena to neurological, physiological, or physio-chemical terms. The explanation of learning is confined strictly to nature. Illustrative is the fact that the language of explanation is heavily burdened with such terms as organism, glandular and nervous mechanisms, behavior. The same materialistic monism also often crops out where the motivation of learning is based on biological satisfaction or the selection of studies is predicated on a hedonistic utilitarianism.

Idealistic monism leads to quite a different interpretation. Here matter is reduced to an aspect of mind—of ideas (idealism is really idealism). Consequently, psychological phenomena, particularly those of learning, are cast in immaterial concepts. Indicative of this change is the more frequent use of such terms as self, purpose, consciousness, and will. Here value is thought of as self-realization, perfection of one's powers in the direction of the ideal. In some idealistic systems there is a monism of will rather than intellect. Such probably was the philosophy back of Froebel's kindergarten.

One of the most famous of all monisms was that of Hegel. Through the employment of an ingenious dialectic, he sought to resolve

the opposition of every thesis and antithesis into a higher synthesis, all topped and enclosed by "the Absolute" (Absolute idea or reason). It is this system which Dewey, the great philosopher of democratic education, says has left a permanent deposit in his thinking. It is also worthy of note for education that the idealistic monism of both Froebel and Hegel tend to be monotheistic.

Finally, reference should be made to the state as a manifestation of the extent to which the "absolute idea" has been able to realize itself in the world. This further extension of idealistic monism is important in understanding the Fascist and Nazi theory of education in the unitary or totalitarian state. While the Nazis decline to acknowledge historical continuity here, the descent of the notion from Hegel to Gentile through Croce is quite clear in Fascist education. (See GERMANY, EDUCATION IN; ITALY, EDUCATION IN.) J.S.B.

MONTESSORI, MARIA. Madame Maria Montessori was, for some years before 1900, an assistant in the Psychiatric Clinic of the University of Rome. She began her educational career as a teacher of defectives and had remarkable success in using and modifying the methods of Sequin and Itard in training sub-normal children. For the instruction of such children she developed a large amount of sense-training material. She lectured extensively on her work, and applied her methods to normal children in some schools which she organized in some tenements in Rome, schools which she called Children's Houses. Her methods aroused a great deal of interest in many countries a few decades ago and were widely adopted. Many Montessori schools were opened in different parts of the United States and the method was for a time heralded as a great improvement over the kindergarten. It is questionable, however, whether her methods have been proved successful in the education of normal children, and they have been somewhat generally rejected by most American educators for any except sub-normal children or those whose

development is retarded. Her practices are based on an outgrown faculty psychology and upon the disputed doctrine of formal discipline, and her schools are generally regarded today as distinctly inferior to the modern American kindergarten.

Madame Montessori believed in training the senses one at a time and invented many exercises and materials, graded strictly, to achieve this end. Visual perception of forms is developed through the handling of solid inserts, many kinds of form boards, and ascending and descending cubes; perception of colors, through learning to distinguish between hanks of silk variously colored; the thermic sense through the perception of the differences between warm, tepid, and cold by dipping the fingers into vessels of water heated to varying temperatures; the tactile sense by giving the child surfaces, rough, smooth, and in-between, to touch and describe; the baric sense by lifting weights; the rhythmic sense by "walking on the line" to the accompaniment of a rhythmic march; and so on. In addition, there are "exercises of practical life"—learning to lace, button, hook on specially constructed frames (preparatory to learning to dress one's self), "making the silence", keeping the room in order, washing one's self, setting the table, and so on.

Madame Montessori holds with Rousseau that "nature is right", and therefore demands complete freedom for the child, yet she restricts his choice of activity to her particular exercises. She says that "auto-education" is the only real education. The child should choose whatever occupation interests him and continue to play or work at it without interference, unless he disturbs other children in the room. Each pupil is supposed to work independently on such materials as he chooses, but the Montessori materials are limited to a fixed number of things that can be handled only in certain definite ways. The games and occupations of Froebel, so valuable for the development of imagination, feeling, and social cooperation, are lacking. Children do not work together in cooperative tasks, and the teacher is an observer of the children's activities rather than a participant in them. Her work, therefore, lacks the social nature that dominates the education of today. Madame Montessori has had considerable success in developing speed and skill in penman-

MORES — MORRISON PLAN

ship, but her method in reading is applicable only to a phonetic language like Italian, and her method in arithmetic is slight improvement over the method commonly used elsewhere. The Montessori method, devised to train the senses and develop an ability to engage in practical activities, continues to have its greatest value in the training of sub-normal children. E.H.W.

MORES. Mores is a sociological term referring to those forms of moral custom which any given society considers essential to its welfare, and which it therefore enforces upon its members through the imposition of general social pressures. Mores differ widely according to period, place, and people, but since they are always the rationalized standard of moral behavior accepted by a given group, they are usually regarded by members of that group as beyond question or criticism.

Mores are distinguished from folkways and law, two other types of social pressures which also influence conduct, the basic difference being in the intensity and the formality of the pressure exercised.

Folkways are those social customs observance of which is desired and expected but not necessarily demanded; for example, use of the proper fork at table, choice of appropriate dress for the classroom, etc. Disregard of the folkways may cause comment to the effect that the individual in question is "ill-mannered," "uncultured," "undesirable," "eccentric," "independent," and the like, but he still may remain professionally acceptable. *Mores*, however, are obligatory folkways, indifference to which is believed thereby to threaten the safety and stability of society itself. Violation of the mores, as in extramarital sex relations, profession of atheism, or public espousal of anarchism, therefore brings charges of "immorality," "heresy," "radicalism," "public menace," "threat to our children," etc., and the violator is probably no longer acceptable either professionally or socially.

Laws and regulations may enforce through formal legal procedures and penalties the observance of folkways and mores; for example, school board rulings may bar married

women as teachers, school law may permit dismissal of teachers convicted of sex immorality, and state law may provide for legal prosecution of sex offenders. The law also may prove impotent to protect innocent violators of the mores, as when members of minority racial and religious groups are denied teaching positions even though discrimination on such grounds may be expressly forbidden by federal, state, and local law.

The teacher must become familiar with the mores and the folkways of the groups with which he deals. The woman teacher who is seen smoking in a restaurant or who accepts a ride from a stranger who is driving to town may not realize how deeply her behavior has shocked the particular community. Understanding the mores and the folkways also will help the teacher to know his students better. The teacher who deals with people different in background from those with whom he has been brought up—as, for example, the teacher whose school enrolls a number of children of a particular foreign-born group—may be unaware of their custom of letting their young children drink wine, or of forbidding their adolescent girls to go on hiking trips unless escorted by an adult member of the family.

If the school is to be an effective social agency in any community, it is essential that both teachers and administrators understand the mores and folkways of the people living there. E.G.O.

MORRISON PLAN. The Morrison Plan is built upon the basic concept that any real learning is expressed as a change in the learner's attitude or as some ability or skill. Morrison classifies these learnings as attitudes of understanding, attitudes of appreciation, abilities and skill (facility). As real learning products, they are termed *adaptations*, because they make a difference in the way an individual reacts. This view emphasizes the contrast between learning the contents of subjects (facts and information) and acquiring significant ways of reacting.

Another basic concept is that there are

MORRISON PLAN

external things to be learned; which Morrison designates as *learning units*. He defines a learning unit for school purposes as "a comprehensive and significant aspect of the environment, of an organized science, of an art, or of conduct, which being learned results in an adaptation of personality." Since learning consists of experience with, and mastery of, learning units, the first problem of the teacher is to determine the units into which a course should be divided.

Still another basic concept of the Morrison plan is that the work of the different subjects taught in secondary education can be classified into five groups according to the nature of its objectives and the learning processes involved. Upon this basis Morrison devised five types of teaching procedure to be used depending upon the objectives sought. These include: (1) the science type, (2) the appreciation type, (3) the practical-arts type, (4) the language-arts type, and (5) the pure-practice type.

After the units have been selected, the next problem of the teacher is to determine the teaching procedures to use. Morrison refers to the actual work of teaching as *operative technique*, during which the units of learning are "developed in the class and in the individuals thereof." It includes the presentation of different materials, supervision of study, testing of pupils, corrective teaching, etc. To guide teachers in systematic teaching, Morrison proposed his *mastery formula*: "Pre-test, teach, test the result, adapt procedure, teach and test again to the point of actual learning."

Many teachers have misinterpreted the basic concept of mastery. Mastery cannot reasonably be applied to a subject or even to a lesson, although teachers talk of the mastery of facts, definitions, dates, or other items of information. True, such content may be important and should be learned, but the concept of mastery applies to the unit-learning as a whole, not to the content or the subject matter alone. That is, there are external things to which we make adjustments, and the resulting learnings are called learning products or adaptations. For example, one form of matter we call a sphere, and the resulting learning product we call a concept of a sphere. Such learning products—concepts or understandings—are acquired

through some kind of experience and are denoted by some name. Thus every learning has an external correlate, and the term unit-learning is applied to both the external correlate or relationship and the resulting adaptation or learning-product acquired by the learner.

Besides our concepts of material things, we acquire concepts of many processes and procedures as unified wholes, such as the process of osmosis. The abilities we acquire represent other types of unit-learnings we use in everyday life. Concepts of social situations, movements, or events such as the "Industrial Revolution" or the "Western Movement in the United States" illustrate the nature of other important unit-learnings.

The acceptance of the mastery concept emphasizes the importance of selecting the unit-learnings that are significant for living and, as far as possible, of helping pupils to master them, that is, to enable pupils to react satisfactorily whenever situations involving such unit-learnings arise. There are thousands of such unit-learnings. The difficulty in applying this mastery concept in school practice lies in the difficulty of determining the most significant unit-learnings to be mastered and in grouping these various unit-learnings into teaching units or course-of-study units for school use.

The term *mastery technique* is applied to the plan of procedure used in developing or teaching unit-learnings, for example, teaching the reduction of fractions or the process of osmosis. For the pupil, it is not a matter of learning a definition or being told a meaning, rather it is his having experience from which meaning evolves. The term mastery technique is also applied to the plan of procedure used in developing a learning or teaching unit in the course of which many different unit-learnings are developed. Whatever the learning situation, learning is concerned with the acquisition of different kinds of unitary adaptations.

Probably the five-step science type procedure is the best known and most widely used of the Morrison teaching types. The teaching steps are: exploration, presentation, assimilation, organization, and recitation. It is planned to be used with science-type units, in which the objectives are adaptations in the form of understandings of principles or proc-

esses in relation to cause and effect. It can be used in such courses as mathematics, grammar, and the physical, biological, and social sciences.

According to Morrison, the techniques that bear his name grew out of studies under his observation in the schools of Portsmouth, New Hampshire, where he was superintendent, and in other schools in New Hampshire, where he was state superintendent of schools. The techniques were perfected in the University of Chicago laboratory schools following his affiliation there in 1919. T.M.R.

MOTHERCRAFT. A term infrequently used today, originally coined by Mary L. Read to cover those aspects of child care which she believed to be the responsibility of mothers. In 1911 the "School of Mothercraft" was opened in New York City by Mrs. Read to provide theoretical instruction and practical experience for young women in the care and training of babies and small children under home conditions. Mrs. Read's book, *The Mothercraft Manual*, published in 1917, was used as a textbook by various other early workers in preparental and parental education (*q.v.*). The first classes for mothers offered in Oklahoma under state auspices were called "Mothercraft classes."

The word "mothercraft" has also been used in England in a somewhat narrower sense, as synonymous with infant care (*q.v.*). B.B.L.

MOTION PICTURES IN EDUCATION. The motion picture today is firmly established in a large number of school systems as an educative instrument of unique value. Not only can the pupil observe motion as though he were present, but through the use of unique angles, close-ups, and other optical devices he is able to get a better view in many instances than he would if he were an actual spectator to the action. In fact through slow motion photography, time-lapse photography (in which unobservable motion such as a flower opening is speeded up so as to be observable), and microphotography, he can see objects not to be seen with the naked eye. The film also eliminates unimportant and extraneous details so that stress is placed

upon the important elements in the situation. With the sound motion picture there is the further advantage of clear explanation occurring simultaneously with the motion, thereby strengthening the total impression. The experimentation which has been conducted in the use of motion pictures has demonstrated the remarkable advantages of motion picture presentation in improving learning, stimulating endeavor, and building attitudes.

Today the 16mm film has been accepted as standard for classroom use because of its availability, inexpensiveness, and ease of projection on portable equipment. The standard one reel subject is 400 feet in length and requires 15 minutes for projection if a silent film, or 10 minutes if a sound film. It is available in a great many subjects, some made especially for school use. There are also a great many industrial or advertising films available, and a great many of these are of acceptable quality, for the producers have found that the best form of advertising is good will. Most of the industrial films show processes and many of the less valuable of these films tend to become monotonous because of their great emphasis upon minute detail, and lack of emphasis upon the social factors in the industrial process. Within the past few years an increasing number of films originally intended for theatrical use have been made available for school use. On the whole these films are of high quality, though the geography films tend to be of the travelogue type which seldom gets inside the homes of the people visited so that we may see how they really live. The U. S. Government films are among the best available on the limited topics with which they deal.

Should a film be silent or sound? There are many advocates of each type of film, but more and more those who use films are coming to the conclusion that both types have their places. If sound is essential to the subject to be taught, then use the sound film. If sound is not essential, then the silent film may be preferred. There is, however, a tendency toward more sound film usage because it more closely approximates reality. It also possesses the advantage of conversion into a silent film by the simple expedient of shutting off the sound. Most schools are now purchasing sound machines for a similar reason; it

MOTIVATION

will run both sound and silent films while a sound film cannot be shown on a silent machine.

The commercial theater has also entered into our national life in a potent fashion which commands the attention of educators. On the one hand it acquaints the pupils with a great many valuable facts about the world in which they live. On the other hand it exposes them to false romanticism, overexcitement, highly emotional situations, and complex problems with which they are not capable of dealing. In some localities considerable attention has been given to the opportunities and problems presented by the commercial film. Good photoplays have been recommended, even sponsored by the school authorities. Courses in photoplay appreciation have been conducted, junior review groups set up, and reviews sent out to parents. Much, however, remains to be done in this important area. (See AUDIO-VISUAL AIDS.)

MOTIVATION. It has taken a long time for educators to recognize that the problem of motivation is much wider than the application of incentives to individuals from whom certain learnings or activities are desired. Increasing emphasis is now placed upon the fact that all human behavior is dynamic or goal-directed. Human goals—the motives which lead individuals to behave as they do—and the possibility of changing these motives are themselves becoming the focus of interest of our schools. Such terms as needs, wants, desires, interests, incentives, attitudes, purposes, values, drives, are all used synonymously with motivation or with some aspect of it, depending partly upon how the writer wishes to distinguish terms and partly upon his theory of the innateness of motive.

Psychologists are not in full agreement as to which motives are universal among mankind nor as to whether the more universal motives have stronger driving power for every individual than have other motives which he has acquired. Most commonly placed among universal motives are the physiologic drives away from hunger, thirst, tiredness, and pain and towards food, drink, rest, sleep, and general physical well-being; the drive away from being bored and towards interesting activity; the drive away from being ignored and unwanted and towards being loved and given some status; the drive toward satisfaction of sex desires; the drive away from feelings of failure towards feelings of success and mastery. Among lists of universal drives or motives that are now offered, we find no specific things which man finds "good" and wants, or finds "bad" and does not want. In the fact that only the desire for food is universal and not the desire for any particular food lies the opportunity for the adults to arrange conditions in such a way that the particular things and the particular ways which the child adopts for gaining satisfactions are in line with, rather than opposed to, the social mores and continuing individual adjustment. No matter what the exact nature of the dependence of motives on innate characteristics may be, there is agreement that the development of values is a social process and that every institution of society, including the school, has a direct influence on the evolution of motives. Many educators are therefore insisting that the school recognize this power which it has and which it cannot put aside, and that every policy of the school and every phase of its curriculum be examined to see whether the influence exerted on the formation of temporary and lasting motives is of the kind desired. (See INCENTIVES for a discussion of motivation from that aspect.)

MUNICIPAL COLLEGES AND UNIVERSITIES. The municipal college or university may be defined as an educational institution devoted to higher education which (a) is controlled by a board appointed by the municipal authorities; (b) is supported completely or in large part by local public funds; (c) requires graduation from a standard high school or the equivalent as a basis for admission; and (d) offers a course of study leading to an accepted degree or degrees. This definition thus excludes from consideration such institutions as junior colleges, adult education centers, normal schools, etc., which are supported and controlled by many municipalities throughout the country. The municipal college, or university, differs too from the urban college or university, which is an institution of higher learning, either publicly or privately supported, established in an urban environment and frequented, at least to some extent, by non-resident students. Normally control of the municipal college or university is lodged in a board of education, or a board of higher education, although it is theoretically possible that the supervisory function may be entrusted to a commissioner of education.

In terms of the above definition, there are twelve such institutions in the United States at the present time. It is interesting to note that only one of them was established by a municipality as a full-fledged college or university. Some were transferred to the public domain from previous private ownership; others developed from institutions which were not on the college level.

The principal aim of such institutions is "to equalize educational opportunity by bringing the advantages of higher education to hundreds who otherwise would be unable to

enjoy them." That this aim has been legitimate is proved by the enrollments in municipal colleges, some of which are very large. Perhaps the development is most striking in states that do not support state universities, but in Ohio municipal institutions have thrived nevertheless. New York City now leads in municipally supported higher education, with day session enrollments normally in excess of 20,000 in four colleges. Wayne University in Detroit is the largest municipal university, and offers professional training in medicine, law, and business administration.

One of the most common reasons why students cannot attend college is their inability to meet the cost, not of tuition fees but of living expenses. The municipal college enables them to live at home and still secure college training. Many students can actually maintain themselves either completely or in part while securing advanced education. In this connection it should be noted that practically all of the municipal institutions conduct evening classes for those members of their student body who are employed during the day.

The several municipal universities show wide variation in many respects—scope of work offered, enrollment, financial support, student fees. The table below indicates some of the differences which appear. It seems rather surprising to find that many of the municipal universities receive a substantial part of their funds from student fees, income drawn from this source varying between 5 and 55 per cent of total operating income. It should be noted, however, that fees are most common in those institutions which provide advanced professional training beyond the baccalaureate degree. The tendency is to keep tuition costs for liberal arts work to a minimum, and to provide professional courses at relatively larger fees. It must be realized, too, that many of the municipal colleges admit nonresidents, who pay much higher fees than do residents of the municipality in which the institution is located.

In so far as curricula are concerned, the municipal university is similar to other private and public institutions throughout the country. The major concern of all the municipal colleges is undergraduate work. Few of the colleges maintain preparatory schools, and graduate work, if offered at all, is looked

MUNICIPAL COLLEGES AND UNIVERSITIES

upon usually as less important than professional and undergraduate training. The municipal college generally offers a four year program of studies leading to the usual baccalaureate degrees. The professional and graduate schools which have been organized conform to the general national pattern for such schools.

It should be noted that the municipal college is normally less experimental and more conservative than are private institutions in the same area, although some municipal colleges have been educational pioneers. The City College of New York, for example, was one of the first colleges to establish a Chair in English, to recognize the importance of speech education in college, and to emphasize laboratory work in the teaching of science. The reasons for the conservatism of the municipal colleges may be that teacher training emphasis is pronounced at most such institutions, and that prudence is exacted of educators directly responsible to urban public opinion. Nevertheless, educators of great merit have governed municipal colleges, notably Thomas Hunter at Hunter College in New York City, John Finley at the City College of New York, Paul Klapper at Queens College in New York, and Raymond C. Walters at the University of Cincinnati.

In academic work, the municipal university is noteworthy for demanding a high level of scholarship on the part of its student body and its faculty. Admission requirements ordinarily are somewhat more rigid than is the rule, and the academic burdens of both student and faculty are heavier than prevail elsewhere. All of the municipal institutions are fully accredited by their regional associations.

Perhaps the most important aspect of the work of the municipal college lies in its service to the city in which it is situated. The municipal institution has made a definite attempt to ally itself with the social, economic, and cultural life of the community. Thus, for example, the College of the City of New York offers many courses designed especially for the benefit of members of the city's civil service employees; the University of Akron, located in the center of the rubber industry, has developed a specialized course in rubber chemistry; the University of Cincinnati maintains a reference bureau, which serves as a clearing house for municipal information, and a testing bureau for the evaluation of city purchases. The contribution of the municipal university to the urban area in which it is located is a convincing reason for its continued support.

Table I
Comparative Data on the Twelve Municipal Colleges in the United States*

College	Founded	First Under Municipal Control	Schools and Colleges in Each	No. of Degrees Offered	Size of Faculty	Size of Student Body	Operating Income	Approx. Operating Income Received from Student Fees (Per Cent)

MUSCULAR COORDINATION — MUSEUMS

The history of the municipal college is an inspiring narrative of courageous leadership. When the City College was founded in 1847 by a group of public-spirited citizens, a publicist commented bitterly that the establishment of such an institution must be considered an unerring indication of "the spread of that Agrarianism which preceded the decline and fall of the Roman Republic". After Thomas Hunter and established the first free training college for women, he had to fight a running battle with commentators who not merely questioned the morality of the undertaking but deplored what they considered the liberalizing of the curriculum. Even in more recent times the tide of opposition has sometimes run high. With the many other demands upon local funds, particularly in times of economic and social stress, an institution of higher education may be looked upon as an unnecessary expense by short-sighted city administrative officials, and demands for curtailment and retrenchment are almost certain to arise again as they have in the past. But it has been demonstrated that when the municipal college is ably led and staffed, and when the attitude of the city administration is based on friendliness and honesty, it finds a large measure of support in public opinion.

MUSCULAR COORDINATION — See COORDINATION.

MUSEUMS. Objects, specimens, and models may be employed in two general ways to add concreteness to the learning process. The objects may be brought into the classroom where they may be seen, handled, and, in some cases, worked with, or the pupils may go to a central repository of such materials where they may see the objects as arranged, displayed, and explained by experts. The first type of experience may be gained in the school museum and the second, in a public museum. Both experiences are important.

A great many schools have developed effective school museums by the simple expedient

of setting aside appropriate room space, providing shelves, and setting a class to work obtaining and arranging exhibits. Museum specimens may be obtained from the school environment, the pupil's homes, commercial concerns, educational supply houses, and public museums. An increasing number of public museums are providing loan exhibits to schools free of charge or for a small fee. It is important that the material be well arranged. Among better forms of arrangement are those which show development, processes, comparison, or contrast. It is important also that all exhibits be properly labeled. The school museum should not be a storage place for worthless curiosities or a glassed-in showplace with a strict hands-off policy. Instead it should be a source of information, a depository from which classes may borrow objects as they would borrow books from a library. It should lead pupils to investigate and experiment and should stimulate a desire to learn more about peoples, places, and things.

The public museum and school should maintain a policy of close cooperation. The museum can help the school by furnishing traveling exhibits, providing lectures and gallery talks, organizing classes, and providing hobby clubs for pupils and teachers. The first of these services is available to schools some distance away from the museum itself, and more and more schools are supplementing the traveling exhibits by conducting class trips to the nearest museums. (See EXHIBITS, EDUCATIONAL.)

The *docent* is the instructor on the museum's educational staff who gives gallery talks and illustrated lectures to visiting classes. In some instances he visits the school with traveling exhibits, offers advice to teachers wishing to utilize the museum's facilities, and serves generally as liaison officer between museum and school. MUSIC APPRECIATION

MUSIC APPRECIATION. The appreciation of music involves more than a pleasurable response; it implies an appraisal of values. When the two are confused, sentimentality is often mistaken for æsthetic judgment. A piece of music then becomes important because of its associations, and when the associations are broken the appeal of the music dies. This is the typical fate of most "popular" music. By contrast, some compositions possess internal strength of æsthetic design and purpose. They continue to live. One might appreciate the personality of the performer or the social use of a piece of music, but to appreciate the music itself he must become attuned to the qualities which make the music expressive. For example, several generations ago the music of Robert Schumann became popular largely through the brilliant musicianship of his wife, Clara. "The most beautiful romance in musical history" undoubtedly did much to color the music of Schumann whenever it was played by his charming wife. Audiences would think of the long courtship, the violent parental opposition, the anxiety of young Robert, and the final triumph of his love, poured out in the music. Yet it was not these sentimental reveries which kept the music of Schumann alive. The famous *Quintet* is played today because it breathes a pure quality of expression, an undefined turbulence of spirit shaped into a musical composition of balance, unity, and coherence.

Music is popularly conceived as a universal language. This is true only in the sense that it expresses human emotions that are universally felt. Such appendages as "moonlight" sonata or "raindrop" prelude may tend to enhance the listener's mood for a time, but eventually the interpretive power of the music itself transcends such limiting descriptions. Appreciation to a large extent is a recognition of those qualities which make music endure.

Aims. Achievement of the following specific aims contributes to the development of music appreciation: freedom of intellectual and emotional response to music; familiarity with the enduring literature of music through singing, playing, and listening; recognition of melodies, rhythms, and structural forms; habits of attentive listening; sensitivity to

tonal color; power to create musical compositions; dissatisfaction with cheapness and vulgarity; and eagerness for sincerity and beauty of expression.

Methods. To appreciate music, children must live with it and feel its power; this involves both performing and active listening. As in other educational enterprises, the teacher can best perform his rôle by creating and utilizing a suitable environment.

In a broad sense a musical environment exists for children regardless of the teacher. In many homes the mother or other family members play and sing. Programs are heard daily on the radio, and not infrequently community groups sponsor varied musical events. Whether or not children attend or participate in these programs rests largely on the educative force of the school. An alert teacher studies the community opportunity for music and creates within the classroom an awareness of its presence and significance. Common methods for this stimulation include the posting of pictures, news clippings, radio schedules, programs, etc., and the discussing of events by those who attend. Organized listening lessons and classroom programs may precede a special musical event outside the school. The teacher himself may perform, children may sing or play representative themes, and appropriate instrumental demonstrations may be used.

Although attendance and participation in actual performance are of prime importance for the appreciation of music, the school can use effectively other methods to improve the musical background of children. A common approach is the study of a national culture expressed in music. For example, an appreciation of the *Peer Gynt Suite* by Edward Grieg may develop with a study of the life and customs of Norway, a reading of Ibsen's play, and a review of the boyhood of Grieg. Books, pictures, narrative description, and contact with Norwegian people serve to promote this background. Such a method is only an approach, however, and should lead to experience with the music itself. Children may listen to recordings, sing principal melodies from blackboard notation, perform on percussion instruments, and, if technically able, play the actual selections. An intelligent teacher will use any such teaching device as impetus for listening or performing, and will

MUSIC EDUCATION

measure its success by the warmth and understanding it engenders in the learner.

Curriculum. For children of the primary grades, the appreciation program generally includes bodily response to rhythm through walking, skipping, marching, and dancing. Such activities give basic experience with pulsations, tempo, and phrase patterns. Singing in a light, clear voice helps to build sensitivity to tone quality. The listening program generally stresses short selections that are strong in mood. The use of percussion and melodic instruments enhances the expression of children and provides opportunity for aural discrimination. By creating their own orchestration children become sensitive to loud and soft, fast and slow, and high and low. Actual performance, under favorable circumstances, creates an attitude of sympathetic understanding toward others who perform. In schools where a unit approach is used, the above activities are generally related to the central purpose of the unit in both content and method. For example, if the unit happens to be a study of the farm, children perform rhythmically in planting the seed, harvesting the crops, churning the butter, etc.

In the intermediate grades children generally experience singing in parts, reading of musical notation, and a listening program of recorded and performed music. The latter usually stresses descriptive music and the use of instruments and voices for musical effects. Such a selection as *Peter and the Wolf*, by Prokofieff, is ideal at this level. Integrated programs involving social studies, art, physical education, and other areas also provide rich opportunities for the development of appreciation.

In the junior and senior high schools, students enjoy three- and four-part singing. Their awakening social consciousness leads them naturally to social music. The appeal of personalities at this level is strong, and the wise teacher utilizes it as an approach to listening and performing. The trials and tribulations of noted composers form meaty substance for interest in music; for example, the fortitude and character of Beethoven, who composed after the onset of total deafness, appeal to hero-worshipping youth. Organized listening programs, such as are listed in the *References*, increase in complexity so that at high school and college levels students are

ready to delve into the structure and varied styles of symphonic music, operas, oratorios, and solo works.

Extensive libraries of recorded music, radio programs, and transcriptions are now available for school use. These, together with an abundance of teaching aids and instructive literature for teachers, make possible a constructive program in even the most remote sections of the country. (See APPRECIATION.)

MUSIC EDUCATION. Since primitive times, music has modified human behavior. Its power to incite joy, suspense, awe, contentment, and conquest was considered by the ancient Greeks to affect the *ethos* and through this the character. During the Dark Ages the Greek tonal systems were altered and preserved by the church. Music education within the monasteries was conducted by the use of illuminated charts, similar in size and purpose to reading charts of present day primary grades. The Renaissance stimulated a development of secular music, the invention of instruments, and new forms of contrapuntal composition, which evolved into our present system of harmony and measured time. During the seventeenth and eighteenth centuries declaimed poetry grew into opera, the miracle play became oratorio, and instrumental ensembles began to take the shape of our modern symphony orchestras. Because of the poor economic and social status of the musician, the music education of youth came usually by grace of royal patronage or by the tradition of folk music within the home.

In America, the early churches of New England frowned upon the use of music. During and after the Revolutionary period, however, the singing school movement grew

MUSIC EDUCATION

in popularity but reached only a few of the total population. It was in 1838 that the Boston school board introduced the teaching of music into the public schools by employing Lowell Mason as instructor. Since that date, music has become a subject of instruction in every state of the Union.

Aims. Music instruction entered the American public schools largely on the thesis that it helped train the mind. Emphasis was given almost exclusively to the reading of music rather than æsthetic expression. It was not until the turn of the century and, particularly, during World War I that the public and the schools sensed more fully the emotional value of music in the lives of young people. Community singing and military bands have contributed to this understanding.

Singing has been and remains the basic activity of public school music. Music reading is still considered a valuable product of public education—not as an end in itself, but as a means toward richer musical enjoyment.

Current statements of purpose generally stress three major aims of music education for the child: (1) to develop an appreciation for worthwhile music, (2) to develop the necessary skills and ability for enjoyable participation, and (3) to develop a desire for expanding and refining the musical culture of the community.

Organization and curriculum. The assignment of music teachers at the elementary level follows two general practices. One requires greater specialization of training and musicianship by teachers and an assignment to several classes. The other requires a basic minimum training of all teachers and an assignment to a single home-room group. At the secondary level, teachers are generally employed who have a special training either in vocal or in instrumental music.

The amount of time given to music in the public school differs widely among school systems. Platoon-type schools (*q.v.*) usually have two to five periods of fifteen to fifty minutes duration a week. Traditional schools often leave the scheduling of music to the individual teacher. Shorter periods recurring daily are generally conceded to produce better results than long periods held less frequently.

A special music teacher who visits among the schools is sometimes employed when cap-

able teachers are not available within a local faculty. This practice is particularly true of instrumental teachers. It is generally discouraged by administrators because of the increased instructional cost of "floating" teachers and because of the separation frequently resulting between music and other school activities.

The function of the music supervisor has gradually evolved from that of overseer or visiting teacher to that of consultant and director. The supervisor, where improved teacher training has freed him from rudimentary instruction of students and teachers, can offer a high type of professional leadership through teaching demonstrations, curriculum development, research, publications, organization of cooperative activities, and community relationships. His assignment seems to be evolving from administrative to advisory activities.

What once was mere "singing" has now become, in many school systems, an elaborate program adapted to individual needs and interests. Required music activities in the elementary schools generally include singing, playing, listening, bodily response, and creative activities. At the secondary levels, where courses are elective, they include general music, mixed choruses, *a-capella* choirs, girls' and boys' glee clubs, instrumental technique classes, bands, and orchestras. A few larger schools offer vocational training in dance music, orchestration and arranging, opera production, radio broadcasting, symphonic repertoire and similar subjects.

Curriculum construction traditionally has been a function of the special supervisor or consultant. It is becoming rapidly a means of in-service training, with students, teachers, principals, supervisors, and the public cooperating in the process. The compilation of data and creation of format are usually entrusted to individuals, committees, or a research department. The construction of courses of study in the more progressive schools is a continuing process, with the course of study bound informally, frequently in looseleaf form, and with bulletins and special reports forming the bulk of the written guide. Content has evolved from textbook determined sentences to a flexible organization of experiences. Octavo music, supplementary books, central libraries of music, radio programs, transcriptions, children's

MUSIC EDUCATION

concerts, and the ingenuity of teachers have all contributed to this movement.

Methods. When Lowell Mason introduced music into the schools of Boston he practiced and preached the teachings of Pestalozzi (*q.v.*) as applied to music. Seven principles governed his teaching method: (1) Teach sounds before signs. (2) Lead the child to observe and discover musical effects rather than have the teacher explain them. (3) Teach one thing at a time, such as rhythm, melody, or expression. (4) Master each step before going on to the next. (5) Give theory and principles as deduction from practice. (6) Analyze and practice elements of articulate sound in order to apply them to music. (7) Have the names of notes correspond to those used in instrumental music.

Teaching methods became the dominating force in music education during the years from the Civil War to World War I. Many devices were used which today have been discarded; others have grown in importance. For example, the alphabetical names of notes were abandoned and replaced by sol-fa syllables. This change persists today. The sensing of time values passed from finger tapping to silent thinking, then to a more overt response than finger tapping (See EURHYTHMICS, DALCROZE). Students were taught to be expert in their power to sing intervals from tonal ladders or modulators. Such methods frequently became ends in themselves and children gained great facility in the use of the device without achieving fluency in reading music from notation.

Accompanying various methods were schools and institutes for teachers, usually promoted by book publishers and leading protagonists of the different methods. Methods became synonymous with basic series of songbooks and the teacher used Mason's method, or later, the Hollis Dann method—the Progressive Method. Since World War I, the training of music teachers has gradually shifted from privately promoted institutes to conservatories and accredited universities. Dominant emphasis on methods, as such, has become subordinated to a program of teacher training and curriculum development wherein a philosophy of education and broad musicianship is prominent.

Today, the emphasis in teacher training has shifted to an understanding of the child, his interests, and the social pattern in which

he lives. The methods used are determined by the teacher's insight into and interpretation of the learner's problems. That the teacher is becoming a strategist of educational opportunities rather than a dispenser of formulae is increasingly evident in more progressive schools. This trend places importance upon flexibility of approach, wide acquaintance with materials, powers of leadership, and a broad understanding of the total educational responsibilities of the school.

Certain procedures are used generally to meet recurring problems. These include the teaching of songs to children by imitation of the teacher's singing, of phonograph records, or of the singing of other children. This is called the rote method of song singing. In the intermediate grades two approaches are generally used for introducing part singing. One emphasizes the use of rounds for development of independence; the other uses simple harmonizations in thirds and sixths, usually as a second part to a familiar melody (such as *Old Black Joe* by Stephen Foster). Much controversy still exists over the approach to music reading. Some maintain that note-reading should be introduced in the first or second grade. Others delay the actual reading of music until grades three, four, or five, depending upon the readiness of the children as exhibited by rote singing, rhythmic response, sensitivity to pitch, and other factors. Details of various methods are contained in the teacher's manuals of basic textbooks and in professional texts.

Professional schools and colleges. Oberlin College, in 1838, was the first institution to introduce music into the realm of higher education. With the expansion of higher education in America, private and state universities have established departments and schools of music, both for general education in the liberal arts and for the training of teachers. Their curricula have generally stressed theoretical subjects. However, some schools give degrees with majors in applied music. Prominent among these are Northwestern University, Yale School of Music, and the University of Michigan.

Professional training for performers and composers has been sponsored largely by conservatories and endowed music schools. Notable among the early conservatories are the New England Conservatory of Music (Boston, 1867) and the Cincinnati Conservatory

of Music (1867). These and similar schools were originally patterned after European models, and employed instructors trained abroad. Today, professional training of the highest excellence is offered by endowed music schools such as the Julliard School of Music (New York City, 1924), the Curtis Institute of Music (Philadelphia, 1924), and the Eastman School of Music (Rochester, 1919).

Trends. The slogan, "music for every child" is rapidly becoming a reality in America. The following trends bear witness to this fact: (1) The war is creating a national awareness of music's contribution to emotional well-being and morale. (2) Musical activities within schools are becoming more closely integrated with life out of school. (3) Music curricula are increasing their variety of offerings in singing, playing, and listening. (4) The human values of music are becoming increasingly important in relation to technical achievement. (5) Music teachers are gaining broader musicianship plus a general academic training and are consequently increasing their powers of leadership. (7) With jazz evolving into a national idiom and the radio pouring forth daily programs, new forces are shaping the tastes and expression of American youth.

Music tests and scales. The evaluation of musical performance is a common experience. The listener who responds to a singer's rendition is testing not only the creative power of the composer and performer but his own power as a receptor. The audience which applauds a performance is expressing judgment of its own aesthetic reaction. The violinist who tunes his instrument to A-440 measures not only the intonation of the strings but his own powers of auditory perception. The teacher who listens carefully to a chorus tests both the performance of individual members and that of the total ensemble. Because of the subjective nature of music, testing remains largely a matter of personal judgment. However, the scientific movement in education has made notable progress toward objectifying and refining criteria and instruments of measurement.

Carl Seashore was one of the first to apply the principles of physics and psychological research to the testing of musical talent. He devised a series of tests, first with laboratory equipment and later with phonograph

recordings, by which he studied isolated musical capacities. His monumental work, *Psychology of Musical Talent* (Silver-Burdett & Company, 1919), initiated a series of carefully conducted research studies in aptitude testing, musical achievement, and aesthetic response.

Aptitude testing. Seashore and his followers have worked on the assumption that measurement of sensitivity to pitch, intensity, time, consonance, melodic memory, and rhythm constitute a profile of capacities which, together with other factors, measures musical talent. They assume that the Seashore tests measure approximate psychophysical thresholds beyond which the learner cannot progress. Such data are used as the basis for predicting probable success of music students. They have demonstrated by investigation that correlations between these factors and general intelligence are low. They have shown also that these factors have predictive value when correlated with grades earned at the Eastman School of Music. Chief criticism of this movement has been made by James L. Mursell and his followers, who believe that musical talent is neither inherent nor can it be measured in isolated capacities. This group would prognosticate probable musical success by measures of aesthetic sensitivity, general intelligence, and musical heredity and environment. They accept the Seashore tests as having merit but believe that they are inadequate without abundant supplementation as an instrument of musical prognosis. The two points of view are not mutually exclusive, but differ in emphasis. Current practice endorses the use of standardized aptitude tests plus informal and subjective observation for the guidance of students.

Achievement testing. Two general types of achievement tests are in current use. One attempts to measure by direct recall the meanings of musical symbols. It is typified by the *Kwalwasser-Ruch Test of Musical Accomplishment* (University of Iowa, 1924). By means of multiple-choice, completion, and matching questions, it tests knowledge of musical symbols and terms, recognition of syllable names and pitch names, detection of pitch and time errors in familiar melodies, knowledge of time signatures and key signatures, note values, rest values, and familiar melodies from notation. It has been stand-

ardized in a large number of cases and is analyzed in the text, *Tests and Measurements in Music*, by Jacob Kwalwasser (C. C. Birchard and Company, Boston, 1927).

The other type of test attempts to measure achievement through performance or æsthetic judgment. Such a test is the *Hillbrand Sight-Singing Test* (World Book Co., N. Y.). This particular test is scored by a trained observer on the basis of established criteria of excellence. It is not standardized. A highly reliable test has been constructed by William E. Knuth and is available in both A and B forms at three different grade levels (Educational Test Bureau, Inc., Minneapolis, Minn.). It consists of a booklet which can be used repeatedly by inserting a simple score sheet. The test items include a series of four-measure phrases which are played at the piano by the teacher. The student has before him a set of melodies, the first two measures of which correspond exactly with what is played. Four optional notations are offered for the completion of each melody. The person being tested selects the one he thinks corresponds with the one played. Objectivity and ease of scoring plus standardized scores make the test valuable both for individual diagnosis and for survey use.

Tests of æsthetic judgment are largely in the experimental stage. Outstanding in this field is the work of Kate Hevner. She has constructed tests by which the listener selects his choice of two renditions, one of which is an original form and one an altered form. Since it is assumed that the composer's original form is æsthetically better than the alteration, students' choices are measured against this criterion.

NARCOTICS. Narcotics is a term applied to drugs such as opium, morphine, heroin, etc., that produce varying degrees of unconsciousness in persons and animals when taken by mouth, inhalation, or injection into the blood stream. They are habit-forming and demand increasing doses to satisfy growing appetites. The vast majority of addicts are adults, most of whom began the use of narcotics after they were grown.

Studies made of addictions reveal that there is no evidence of the use of narcotic drugs among children. Adolescents, however, seem to be in greater danger. More of them have attained relative freedom from the control of the home and have more spending money which they have earned. These facts increase their opportunities to escape from the strains and stresses of middle and later teens by securing and using narcotics. Such adolescents are persons who have already developed faulty personality habits of evading rather than facing unpleasant situations. The prevention of and protection against drug addiction hinge, then, on the nature of the personality. Since the development of healthy personalities is the chief job of the schools, prevention becomes essentially a school function. The adolescents' desire for new and exciting experiences also may lead them into the use of these dangerous drugs.

In certain high schools in that part of the U.S.A. bordering on Mexico there have been sporadic cases of students who smoked cigarettes made of *marijuana*, a plant grown chiefly in Mexico. The effects of this drug are extremely disintegrating to the personality. Thorough investigations into these cases of

marihuana smoking indicate, however, that the reports have been greatly exaggerated. M.S.Q.

NATIONAL CATHOLIC EDUCATIONAL ASSOCIATION. The object of the Association is to promote and safeguard the interests of Catholic education through study, conference, discussion, and publication. The annual meeting is held during the Easter vacation. Proceedings and addresses are released in the Annual Report and special bulletins published quarterly. The Association includes the following departments and sections: college and university, secondary-school, superintendents, parish-school, deaf and blind education, and seminary. Though no authority is exercised over Catholic schools, since control is vested in the Ordinary of each diocese, the influence of the N.C.E.A. is quite directive and extremely beneficial. Funds for support are derived from membership (sustaining, school, and general) and special donations. The President General is a member of the Hierarchy. The office of the Secretary General is 1312 Massachusetts Avenue, N.W., Washington, D. C. The membership is approximately 3,500; the annual income, \$25,000 (1942). (See ROMAN CATHOLIC EDUCATION.) NATIONAL CONGRESS OF PARENTS AND TEACHERS. A federation of parent-teacher associations (See HOME AND SCHOOL COOPERATION), which includes many,

NATIONAL DEFENSE, VOCATIONAL TRAINING FOR

though not all, of these associations in the United States. Organized in 1897 under the name of the "National Congress of Mothers," the National Congress of Parents and Teachers now maintains branch organizations in every state and in most cities, and has a total membership of nearly two and half million (as of 1940-41). Publications of the National Congress include *The National Parent-Teacher*, formerly called *Child Welfare Magazine*.

B.B.L.

NATIONAL DEFENSE, VOCATIONAL TRAINING FOR. In May, 1940 the United States Office of Education prepared estimates and proposals for greatly expanding the program of vocational training for national defense. The U. S. Commissioner of Education, John W. Studebaker, proposed that the then available training resources of the public trade schools be fully used, that these facilities be expanded, and that the resources of the engineering colleges be utilized. The splendid way in which public and private schools, both secondary and collegiate, responded to the challenge is now a matter of record.

Within 18 months of the time the proposals were made, approximately 4 million persons were being trained, either through the regular program of vocational training or through classes under the defense training program.

Many agencies are sponsoring training for national defense. The United States Office of Education, in cooperation with State Boards for Vocational Education and with thousands of local boards of education are administering programs such as these:

1. *Trade and industrial training of the pre-employment refresher type.* The purpose of this training is to prepare unemployed persons with single skills that can be used effectively in defense industries. (See VOCATIONAL EDUCATION.)

2. *Trade and industrial training that is supplementary to employment.* This training program seeks to prepare men employed in national defense occupations for more responsible jobs essential to national defense.

3. *Training out-of-school rural and non-rural youth.* This is done through instruction that will increase the effectiveness of youth for the defense of American democracy.

4. *Training for N.Y.A. enrollees.* The ob-

jective is to teach vocational skills, under public school supervision, through instruction related to the work experiences given by the National Youth Administration (q.v.).

5. *Engineering training*, later known as *Engineering, Science, and Management War Training*. This program is administered by the U. S. Office of Education in cooperation with accredited engineering colleges. The purpose of the program is to provide qualified personnel for engineering, science, and management jobs essential to the war.

Another program is sponsored jointly by the U. S. Office of Education and the Civil Aeronautics Administration. Its chief purposes are to provide airport attendants and other ground workers at airports.

Apprentice Training. Apprentice training is promoted by the U. S. Department of Labor, Division of Labor Standards, Apprenticeship Committee, working with state departments of labor, as well as by the U. S. Office of Education, in cooperation with State Departments of Education and local boards of education. (See APPRENTICESHIP EDUCATION.)

Civilian Pilot Training. The U. S. Department of Commerce, Civil Aeronautics Administration, with the aid of colleges, universities, and civic organizations selects persons who are well adapted for jobs as pilots, gives ground and flight courses approved by the C.A.A.

Army Air Corps. The War Department, Air Corps, sponsors a number of training courses in order to supply vocationally competent persons to service and repair all types of military aircraft. Individuals are trained for such jobs as airplane mechanic, armorer, welder, sheet metal worker, aircraft electrician, propeller specialist, assembly specialist, machinist, and instrument repairman.

Training in flying is also given by the Air Corps. Men are trained to be navigator-gunners. Qualified men are also given training to enable them to become air corps squadron communication officers. Air corps squadron engineering officers are also trained. (See MILITARY EDUCATION.)

The Navy. The Navy administers an extensive program of training for naval aviation cadets. This instruction leads to a commission as ensign in the U. S. Naval Reserve, and offers an opportunity for a commission

in the regular Navy. The training also qualifies for pilot or for technical ground work with aircraft transportation service.

Maritime Commission. The U. S. Coast Guard gives training for the U. S. Maritime Commission, centered upon furnishing trained seamen for the U. S. Merchant Marine. This includes training for apprentice seamen, unlicensed seamen, and licensed officers.

The Maritime Commission also administers instruction for maritime cadets who are trained to become officers in deck and engine departments of merchant ships or U. S. Army transports, and cadet officers for ships of the U. S. Merchant Marine or U. S. Army transports.

Training Within Industry. The Office of Production Management established the "Training Within Industry" service in order to assist defense industries in meeting urgent needs for skilled workers and supervisors. The program is in charge of a director, an associate director, headquarter assistants, and a field staff. In 1941 the field organization was set up in 22 districts, representing all parts of the United States. The organization renders specific advisory assistance to defense industries. The assistance given includes (1) help in the analysis of training needs, (2) aid in setting up plant training programs, (3) making available the experience of other employers through headquarters and field clearance, (4) interpreting the needs of industry to government, state, and local agencies.

NATIONAL EDUCATION ASSOCIATION. The National Education Association is the largest national organization of teachers in the United States, numbering approximately 185,000 classroom teachers and ad-

ministrators. The organization is an outgrowth of the older National Teachers Association, which came into being in 1857 as a result of an invitation by ten state associations of teachers to all teachers in the country to form a national society.

Before 1900, membership in the association was small and unstable and the influence of the organization relatively unimportant. From 1870, the date of the formal founding of the association, until 1900 the membership increased from approximately 300 to 2,322. In the next twenty years, membership rose slowly to almost 10,000, and by 1923 it leaped to more than 118,000. This phenomenal increase in such a short span of years may be attributed in large part to the adoption, in 1920, of a plan of organization providing for government of the association's affairs by a representative assembly, composed of delegates from affiliated state and local organizations. This new procedure made it impossible for a group of teachers residing near the convention city to dominate, by sheer numbers, the proceedings of the national convention and the election of officers, and thus control the organization. Membership increased markedly when teachers who were unable to attend the convention found it possible to participate in the affairs of the association though the election of delegates.

With the growth in membership, the N.E.A. increased its services to the teaching profession. Since 1922, a research division has been active in investigating such professional problems as teacher tenure, the teacher's economic position, the nation's school building needs, the improvement of social studies instruction, and many others. In addition to making available the findings of its research division, the N.E.A. publishes a monthly journal, a volume summarizing the proceedings of its annual convention, and yearbooks and reports of its various departments.

The establishment of departments as a means of meeting the needs of special groups of teachers is another of the factors responsible for the tremendous growth of the association. At the present time, there are twenty-four departments (e.g., the Department of Superintendents) which, while functioning within the framework of the organization, provide teacher groups with an opportunity

to discuss problems relating to their own special educational fields.

In addition to the activities already noted, the National Educational Association assumes major responsibility for the preparation and dissemination of materials relating to the celebration of American Education Week, and participates in the presentation of nation-wide radio programs. The N.E.A. was instrumental in the organization of the World Federation of Education Associations. The National Educational Association cooperates with local and state teachers associations, and with the U. S. Office of Education in research and publication. Perhaps the most important work of the association at the present time centers about the Educational Policies Commission (*q.v.*), organized in 1935. J.J.

NATIONAL RESEARCH COUNCIL —
See COUNCILS OF LEARNED AND PROFESSIONAL SOCIETIES.

NATIONAL SOCIETY FOR THE STUDY OF EDUCATION. This society was first organized in 1895 by a group of educators assembled at the Denver meeting of the National Education Association. It was named the National Herbart Society in apt appreciation of the source of stimulation of the serious interest of leaders of the organizing group in the scientific study of educational problems. The first executive council, which continued in office from 1895 to 1899, included Charles E. DeGarmo (president), Elmer E. Brown, Nicholas Murray Butler, John Dewey, Wilbur S. Jackman, Frank M. McMurry, Levi Seeley, C. C. Van Liew, and Charles A. McMurry (secretary). Five yearbooks and six supplements thereto were published by the society. They were made available for general distribution but were designed primarily to serve as the basis of discussion at national and regional meetings of the members.

In 1901 the society was reorganized under a new name, the National Society for the Scientific Study of Education. The obvious intent was to continue the prior emphasis on scientific studies of educational problems while recognizing the desirability of broadening the base of the society's studies and dis-

cussions to accommodate the emerging problems of a rapidly expanding system of education. In 1909, following several attempts to agree upon a shorter name for the organization, the word *scientific* was eliminated from the title and the present name of the society was adopted. Membership is open to all persons interested in promoting the purposes of the society, namely, to carry on the investigation of educational problems, to publish the results, and to stimulate the discussion of these publications. The present membership is about 1200 (1943).

The tradition of discussion meetings for the critical review of the yearbooks of the society has been maintained, each yearbook being formally presented to the membership at one or two program sessions of the annual meeting of the society held in conjunction with the February convention of the American Association of School Administrators. The selection of topics for treatment in the yearbooks has steadily broadened in response to the changing concepts, the innovating practices, and the extending researches which characterize the development of educational programs in America since the turn of the century. The forty-two yearbooks published since the reorganization of the society in 1901 cover topics of major interest to educators at the time of publication, and the series as a whole provides a serviceable overview of significant movements in education throughout the period. The demand for the yearbooks has developed to such proportions that the publication program is now the dominant feature of the society's activities.

The yearbook is published annually in February, usually in two volumes covering two separate topics of current interest. Each volume is prepared by experts in the field of the subject under consideration. Under the supervision of the board of directors of the society, a committee is selected to assume the responsibility for the preparation of each volume. The prestige attained by this series of publications is a notable tribute to the work of hundreds of members of the profession who have contributed time and talent to the enterprise.

As organized in 1901, the officers of the society were the president, secretary-treasurer, and an executive committee of four members. In 1909 a board of trustees of three members was established to serve as custodian of

property and to direct the financial transactions of the society. The office of vice-president was created in 1913. The constitution was revised in 1924 with provision for a board of directors to have complete charge of all of the affairs of the society. Two members of the board are chosen each year by vote of the members of the society, the term of office being three years. The secretary-treasurer is selected by the directors and is *ex officio* member of the board. After the death of Dr. Guy Montrose Whipple, secretary-treasurer for twenty-six years, the executive office of the society was moved to the Graduate Education Building of the University of Chicago, 5835 Kimbark Avenue, Chicago, Illinois. Until 1916 the yearbooks published by the society were distributed by the University of Chicago Press. From 1916 through 1942, the commercial agent for the sale of the yearbooks was the Public School Publishing Company, Bloomington, Illinois. In January, 1943, the agency was assigned to the Department of Education of the University of Chicago in order that the distribution of the yearbooks might be more readily coordinated with other activities of the society under the supervision of the board of directors. A complete stock of all yearbooks heretofore published by the society is maintained, single copies or full sets being available on order addressed to the present distributing agent.

N.B.H.

NATIONAL SURVEY OF TEACHER EDUCATION. In 1928, the American Association of Teachers Colleges, the Council of State Superintendents and Commissioners of Education, and the National Association of Deans of Education made a joint request to the Federal Government to include a survey of the education of teachers in the government's program of national surveys. The United States Commissioner of Education at the time, Dr. William John Cooper, with the assistance of these three organizations, procured from the Seventy-First Congress authority to make a survey of the education of teachers which was to extend over a period of three years and was not to cost in excess of \$200,000 (reduced later to \$180,000).²

This survey included a study of the qualifications of teachers in the public schools, the supply of teachers, and the facilities available and needed for teacher training, in-

cluding courses of study and methods of teaching. The National Survey staff pointed out, among other things, that the privilege of educating teachers should be reserved to institutions which are equipped adequately to do the job; that the state has a basic responsibility for teacher preparation; and that there is great need of a professional attitude towards teaching in all teacher-training institutions. A critical evaluation of the survey appears in the *Twenty-Third Yearbook of the National Society of Teachers of Education*.¹ (See TEACHER EDUCATION.)

NATIONAL TEACHER EXAMINATION—See TEACHER EXAMINATION, NATIONAL.

NATIONAL YOUTH ADMINISTRATION, EDUCATIONAL WORK OF. The National Youth Administration (hereinafter called the N.Y.A.) was established by executive order of President Roosevelt on June 26, 1935, as an autonomous division of the Works Progress Administration, and with certain modifications and recent limitation of funds has continued to the present (1943). In 1940, the N.Y.A. aided 448,000 persons in its student work program (total earnings \$26,835,000) and 326,000 persons in its out-of-school work program (total earnings \$65,211,000). Its original general purpose was two-fold, namely, to provide funds for the part-time employment of needy school, college, and graduate students, 16 to 24 years of age, to enable them to continue their education, and to provide funds for the part-time employment of youth from relief families on work projects to provide valuable work experience and to benefit communities. Of these two programs, the former is generally termed the student aid program, conducted by college and public school officials, and the latter, the works project program.

In recent years the principal modifications have involved training, as well as work, for needy youth, an increasing liberal definition of "needy youth," greater independence of

NATIONALISM IN EDUCATION

status for the N.Y.A., and a redirection of the works program toward specific training of youth for war industries.

The administrative organization includes a national executive director (who serves also as deputy administrator of the Works Progress Administration), regional directors, state and district directors, and local project supervisors. A rather elaborate plan of national, state, regional and local advisory committees, and special advisory committees for the student aid program has been put in operation to aid in the formulating of general policies and operating regulations.

Educationally, the N.Y.A. has performed five general functions:

(1) The administration of the student aid program for high school, college, and graduate students, by which needy, worthy youth were enabled to enter and remain in school while working at various jobs designed to provide valuable work experience, either within the school or on off-campus public service assignments.

(2) The works projects program, which was designed principally to give out-of-school youth work experience and allied educational and vocational training to enable them to be placed in private employment. In 1942-1943 this phase of the program was concentrated increasingly upon intensive, short-course training for specific wartime industries.

(3) The guidance and placement service, which was designed to provide counsel and orientation for youth in occupational training and placement. In this connection, several comprehensive studies of youth were made by various agencies, thesis writers, and other research workers.

(4) The apprentice-training program undertaken by the N.Y.A. This was short-lived and was soon transferred to the Department of Labor, cooperating with the State Boards for Vocational Education that had similar programs already in operation in the states.

(5) The program of educational camps for unemployed women, which was of experimental nature and was found too expensive to maintain; it was replaced later by central training units for needy feminine youth in residence.

In a widely-discussed publication (Reference No. 5) the Educational Policies Commission of the National Education Association and the American Association of School

Administrators set forth views urging, as a matter of policy, the transfer of the educational functions of the N.Y.A. and the C.C.C. to regularly established national, state, and local public educational agencies, the gradual discontinuance of both emergency agencies, and the transference of the work function to the general agency or agencies of public works.

The experimental educational phases of the program of the N.Y.A. should provide an excellent foundation of experience for future ventures likely to be necessitated by the precipitous problems of the postwar era.

NATIONALISM IN EDUCATION. Nationalism in education aims, in its ultimate analysis, at the preservation and glorification of the state. The nationalist looks upon education primarily as an effective agency in the carrying out of governmental functions. The maintenance of education is considered a patriotic duty. The nationalistic philosophy conceives of education as having its greatest values in the provision of military preparedness and aggressiveness, the development of national wealth and economic independence, and the promotion of national unity through common ideals and traditions. Nationalism recognizes that education is an instrument which the state can use to defend and maintain itself and to achieve its nationalistic ideals; it believes that the state must depend upon education if it wishes to safeguard

NATIONALISM IN EDUCATION

itself against internal disintegration and external aggression. Few would question the efficiency of a national policy of education as a means of promoting national ends.

The principle of nationalism has been one of the most powerful influences upon the establishment of schools in the whole history of education. It was nationalism that stimulated the organization and development of the state-supported and state-controlled public school systems that are to be found almost everywhere in the world today. Wherever there has been the growth of a strong nationalistic spirit, there "schools and the means of education" have been encouraged and utilized as powerful agencies for the perpetuation and protection of the nation. Monarchies and republics alike have accepted the establishment and maintenance of public schools as a national policy. Nationalization of education has taken place under both the totalitarian and democratic forms of government. Under the former, education has been promoted to produce obedient, loyal, and efficient subjects; under the latter, education has been fostered to equip citizens with the knowledge, skills, and attitudes necessary for participation in a free representative government.

The concept of education for national ends arose as a defense reaction on the part of threatened peoples, and when a nation is at war the nationalistic philosophy of education is very likely to become dominant. The nationalistic policy of education in modern times originated in the French Revolution when the people were called upon to defend their newly won liberties against a coalition of foreign kings. The leaders of the Revolution, recognizing the need of keeping alive the patriotic impulses born among the masses of the French people, advocated the establishment of a state system of education through which the people might be informed of the advantages of the new system of government and instructed in their rights and privileges under the new order. Although they did not remain in power long enough actually to establish a workable system of state schools, such leaders as La Chalotais and Condorcet set forth in their writings the aims and purposes that were to dominate the national school systems established during the nineteenth century in many other countries, particularly Prussia and the United States. After

the crushing defeat of Prussia by Napoleon, Fichte advanced the idea that education's function was primarily that of building up and preserving the national welfare, and that the government must consciously control education and the schools to that end. Thus was begun a policy which has continued in Germany down to the present day, the control of the schools for the purpose of developing loyalty to the ruler and the nation and unqualified obedience to the laws of the state.

Nationalism has been a powerful force in the development of public school systems in the United States. A distinction should be made, however, between the traditional nationalism of a totalitarian state with its conception of citizenship based wholly on loyalty and unquestioned obedience, and the American ideal of a participating citizenship that develops its national loyalties out of a spirit of creatively cooperative effort.

Today a fundamental motive in education in the United States is the desire to use the schools to prepare our youth for citizenship in both state and nation. President Roosevelt voiced the sentiments of most of his predecessors when he said that the only way in which the representative form of government can persist is through an educated electorate. (See CITIZENSHIP, EDUCATION FOR.)

Nationalistic principles of education in accord with the totalitarianism of such countries as Germany, Italy, and Japan are motivated by a different spirit from that determining the educational principles and practices of a democracy. Germany, Italy, and Japan have established systems of mass education aimed at making their totalitarian forms of government successful. (See GERMANY, EDUCATION IN; JAPAN, EDUCATION IN; ITALY, EDUCATION IN.) For example, the Fascist leaders have taught through their schools that the individual is an instrument of the state; that the state has rights, but the individual has only duties. The slogan of Fascist education is "Believe, obey, fight." Hitler said most truthfully, "I have not educated German youth for twenty years for naught." Children have been thoroughly indoctrinated with the Nazi theories, and teachers have had to gain political approval more commonly than academic approval. In all school systems, democratic as well as totalitarian, provision is made for the careful training and selection of teachers by the

NATURAL CONSEQUENCES

state. Teacher-training institutions have been established under state control, and systems for the examination and certification of teachers developed. Even in the democratic nations, the question of academic freedom (*q.v.*) has sometimes arisen as an educational issue.

The nationalistic ideal emphasizes primarily secular and civic education; where religious and moral types of education are preserved, these are considered usually as agencies in the promotion of patriotism. Law-abiding morality is recognized as an essential of patriotic citizenship. Physical education is also considered an essential element in national school systems. The totalitarian schools place special emphasis upon training for health and physical vigor, parenthood, "racial purity," and strength. With the entering of the United States into World Wars I and II, physical fitness programs for more and better physical training were promoted in our schools. Vocational training also is given emphasis by national governments, especially for the rank and file of the people, who must be made vocationally efficient if the nation is to survive in its economic struggles with other nations. Nationalistic education is usually universal, compulsory, and even free, although seldom common in the true sense of providing equality of opportunity to all. Support is usually by taxation, and control is in the hands of officials appointed by the party leaders, if the government is totalitarian, or by the elected representatives of the people, if the government is democratic.

One of the most important steps in the development of nationalism is the creation of a common culture and unity of attitude, and so national language, literature, and art usually are emphasized in the schools of a nation. Next in importance to nationalistic educators is the teaching of the history and geography of their countries, although in the preparation of history texts no nation has been overzealous in presenting the whole truth, and history is often distorted in order to make it contribute to national ends. The central feature of most nationalistic courses of study is government and the duties of a subject or citizen. In the United States the teaching of "civics," as it is called here, has not only been emphasized but, especially in recent years, has been required by law.

Patriotic songs and martial music are dominant in national schools, in totalitarian states at all times, and in the democratic states at such critical times as when the nation is involved in war.

The world wars of our century have awakened in many educational leaders the realization of the inadequacy of any nationalistic policy of education that serves to develop a nationalism either imperialistically aggressive or provincially isolationist in character. They contend that national democratic ideals cannot thrive in a world of suspicious neighbors, and that national democratic citizenship achieves its full fruition only if directed toward the ideal of world citizenship. The failure of the League of Nations has served to emphasize the impossibility of achieving a community of nations out of a membership dedicated each to his own self-interest. E.H.W.

NATURAL CONSEQUENCES. The inevitable or necessary results arising from any set of conditions are *natural consequences*. They are the logical outcomes of a given situation. If painful, they are known as natural punishments; if pleasurable, they are thought of as natural rewards.

Natural punishment is the pain or suffering resulting as a natural and inevitable consequence of one's own misdeeds. Rousseau (*q.v.*) in his *Émile* made natural punishment part of his system of instruction. *Émile* thoughtlessly trampled a neighbor's budding bean patch, and his punishment was to retill the garden, plant a new crop of beans, and tend them carefully until harvest time. His thoughtlessness had deprived the neighbor of his beans; his punishment was that he restore them in such a way that the neighbor was not inconvenienced and that *Émile* himself realize

to the full the natural consequences of his thoughtlessness. The great advantage of natural punishment was held to be the removal of the personal element. Émile was not punished by his tutor, but by his own misdeed; no one but Émile suffered from his thoughtlessness.

The theory has obvious limitations. The most serious is that the severity of the punishment may be out of all proportion to the need for it. For example, the child who cheats on his homework may be punished eventually if he realizes that he has not mastered the material and thus receives a low grade as a result of his poor work, but, until then, should he be permitted to drift and later, perhaps, spend six months repeating the work of the grade? Again, his experience at cheating may lead him to believe that "crime" actually seems to pay and that his dishonesty appears to have helped him get a higher grade. Nature is not a reliable moral guide—it goes its amoral way unhampered by the responsibility of guiding the ethical development of each little transgressor.

The parent and the teacher will find it necessary to substitute insight and understanding for the oversights of nature. However, punishment should *seem* to the child to be a natural consequence of the offense. The child who is repeatedly careless in his homework assignments is asked to stay after school to do his work under the teacher's guidance. The teacher explains to the child that since he has demonstrated his inability to do his work at home, it is up to the school to afford him the facilities and guidance he apparently needs. Nothing of retribution is involved; if he cannot do his work at home, then "naturally" it is up to the teacher to give him the opportunity of doing it in school. The spirit is that of natural punishment, even though the form is artificial. (See PUNISHMENT.)

NATURAL PUNISHMENT—See NATURAL CONSEQUENCES; PUNISHMENT.

NATURALISM. The precise meaning of naturalism in education depends on its context, particularly on what can be inferred

as to its antithesis. One of the oldest and most persisting contrasts here is that between the natural and the artificial. The artificial points to something made by the art of man. Whether this handiwork be customs or schools, it will probably vary with time and place and man's individuality. The natural, in contrast, suggests great stability; it suggests the form things have had from the beginning (nature from *natus*, the past participle of *nasco*, to be born). This stability or dependability is more often known as the uniformity of nature.

A second contrast of long and important standing is that between the natural and the supernatural. Here the natural supposes that the explanation of the form of things as they are, is immanent in the physical universe and that unsolved riddles are to be approached empirically. The supernatural, by contrast, supposes that the natural offers only a limited and partial understanding of total reality. To understand what lies beyond nature one must ultimately depend on revelation.

Both of these interpretations of naturalism have affected the theory and practice of education. The first was involved in the contest between the Sophists with their educational cliché of "man the measure of things" and their critics who sought more or less to conform education to the law or uniformities of nature. The second became prominent as the Christian influence on education tended to demote the importance of nature, because of its fallen or corrupt character, and exalted the divine or supernatural. It was not, however, till Comenius in the seventeenth century and especially Rousseau in the eighteenth that naturalism became a *cause célèbre* in education.

Negatively, naturalism came forth as a protest movement. For one thing, as might be expected, it was directed against an education overburdened with the barren subtleties of theology and metaphysics. For another, it was directed against artificial convention represented on the one hand by the brittle and superficial formalism into which humanistic education had fallen and on the other by the stilted social institutions of the eighteenth century. Positively, naturalism not only re-emphasized the study of the rapidly growing natural sciences, but it also proposed the study of the child, not in opposition to nature

NATURE STUDY

as hitherto, but himself and his fellows as a part of the system of nature itself and his natural tendencies as the worthy point of departure for self-development.

It is from this source that the child study movement of the nineteenth and twentieth centuries stems. In this period, the scientific study of the child through the sciences of biology, psychology, and sociology thoroughly saturated education with the spirit of naturalism. To such an extent did education become naturalized that its aims were increasingly found inside nature; the natural and social sciences finally gained an ascendancy over the humanities in the curriculum; even moral education was often secularized; and the philosophy of education became prevalently pragmatic and experimental.

Formidable as this movement has become, it should be remembered that it has not totally eclipsed its old rivals, humanism and supernaturalism. Whether the teacher or society should guide (interfere with) nature or let nature take its course and whether a scientific and pragmatic education without reference to an immortal soul, to God as the origin and destiny of the child, and to grace and revelation as means of human improvement, is adequate, are questions which humanists and especially Catholics still press as energetically as ever.

NATURE STUDY. In its widest sense *nature study* means the study of all natural phenomena and is thus synonymous with natural science. By general agreement among writers, the meaning of the term has been restricted to include only simple observation of natural objects and the acquisition of information about them to satisfy personal curiosity, to meet simple practical needs, or to develop positive emotional attitudes towards the natural environment.

Nature study contrasts with natural science chiefly in that the latter, while incidentally attaining the ends just enumerated, seeks primarily to establish principles and generalizations in terms of which large areas of experience are explained and integrated. To the nature student the ardor with which a mother rat cares for and defends her young is significant for its intrinsic interest, its warning value, or its appeal to human sympathy; to a scientist it is a phenomenon to be compared and contrasted with analogous behavior in other species, to be explained after painstaking experimentation in terms of prolactin or other humoral or neural causes, and to be recognized in its proper relation to the perpetuation of the species.

Observation and description are the methods of nature study with little, if any, admixture of such other methods of science as exact quantitative recording, controlled experimentation, analysis, guarded inductive inference, classification, generalization, and proof. Characteristic procedures for young children of elementary school age include going on field trips, making collections, caring for pets, participating in dramatizations of their nature study activities, correlating nature study with literature, social studies, and the expressive arts, participating in informal discussions, and conducting various forms of manual activities, such as building bird houses.

As most frequently used, the term nature study is the designation of a part of the curriculum of the elementary school, but abundant instances may be cited in which its sense is extended to include similar study in the higher schools and even the out-of-school pursuit by adults of interests in nature. While the methods of nature study are suitable to the young for whom the more exacting methods of science are not yet possible, it does not follow that nature-study is not also adapted to the needs and abilities of adults. The lives of great naturalists such as Thoreau and Audubon, the popularity of adult hiking and nature clubs, the National Park Service of the Federal Government, and the wide popularity of nature books and magazines, lectures, and moving pictures are all convincing proof that nature study is not merely a matter for children.

Animals and plants constitute the principal field for nature study, especially the appear-

ance, habits, and life history of the organisms. Little attention is paid to internal anatomy, physiology, or systematic taxonomy. Rocks, soils, air, weather, and the heavenly bodies are commonly included in the scope of nature study, but physics and chemistry, whose subject matter consists essentially of principles, are for that reason given little attention.

The nature study movement in the elementary schools both in America and England covers roughly the last decade of the nineteenth century and the first two or two and one-half of the twentieth. Antedating it and probably leading up to it was the movement for "object-teaching" which drew its inspiration from Pestalozzi and was promoted by E. A. Sheldon and his associates at Oswego. William Torrey Harris, W. S. Jackman, and others protested in their writings against the dry formality of early attempts to teach science to elementary pupils and urged the livelier methods of nature study. As a result of the strong recrudescence of science teaching in American elementary schools after 1925, the subject is commonly designated as "science" or "elementary science," but, especially in the lower grades the methods, the spirit, and the content of so-called nature study remain dominant. (See SCIENCE, TEACHING OF.

NAVAL EDUCATION—See MILITARY EDUCATION.

NEAR-SIGHTEDNESS—See, VISION.

NECESSITARIANISM. Necessitarianism is the world view that (scientific) causation has already fixed in precise detail all future events so that in particular no room is left for "personal freedom," for practical responsibility, or for moral obligation. Such cosmic

determinism (or pre-determinism) is a doctrine of metaphysics rather than the result of scientific induction. It is the modern version or successor to the earlier doctrines of fate and predestination.

To the ancients fate seemed to mean that at least certain important, and possibly all, outcomes were fixed in advance—not indeed in terms of what moderns call causation but rather in spite of intermediate steps and efforts. Seen in this light, such a belief remains now only as a superstition.

Predestination seemed to the theologian the necessary consequence of God's power and God's knowledge. He made all things, He chose how all history should turn out, He foresaw all the details. The result thus appeared to Omar Khayyam:

Yea, the first Morning of Creation wrote
What the last Dawn of Reckoning shall read.

Alexander Pope saw the result in terms of "free will":

And binding Nature fast in fate,
Left free the human will.

How to reconcile predestination and "free will" has been one of the abiding problems of theology. To the ordinary mind at least they seem antagonistic. Certainly if all future events have now been already fore-fixed in every detail, contingency loses its customary meaning if not all validity, while in consequence neither concern, nor effort, nor responsibility, nor moral quality could mean what now they seem.

Under modern science with its (earlier) insistence on causation as always and everywhere present and effective, the same problem of man's freedom to choose and effect presented itself, with physics seemingly on the side of predestination. Laplace, for example, not willing with Pope to leave "the human will" outside of Nature, thought that to an all-seeing intelligence, with causation everywhere at work, "nothing would be uncertain and the future, as the past, would be present to its eye." In other words, time also would go. Since this day many scientifically minded have "in theory"—but never in actual everyday affairs—accepted this view. It is this doctrine which we may call neces-

sitarianism (or cosmic determinism, or pre-determinism).

So strongly did this cosmic determinism become entrenched that many a scientist heaved a sigh of relief when the quantum theory seemed to support a principle of indeterminacy (Heisenberg's) for micro-physics. Now, thought they, we have sufficient leeway to admit a real place for effective human thinking and consequently for the long-needed human freedom and responsibility.

However, it seems sufficient to say that no empiric position is better established in human experience than that planning and effort do, within limits, change the course of events. To use scientifically established uniformities of nature thus to deal with a contingent situation is not to deny "causation," but to use it for precisely what it is worth. Such a view of determinism as over against "necessitarianism" assures to the scientist all the causation he can in fact prove, while it saves for the practical man and the moralist the "freedom" they demand.

It may be asked, What has necessitarianism to do with education? The answer comes as we consider the growing significance of social change in modern life and the increasing place of education in shaping that change.

So long as change did not obtrude itself strongly, man was content to accept more or less consciously one or more of the pre-deterministic outlooks, fate or predestination or necessitarianism. On either basis thinking became, consistently, a mirroring of what was otherwise fixed. Man did not, at least in any significant degree, change events. At most or at best he saw them, his thinking if correct reflected them. In the then prevailing opinion man was responsible for his soul's salvation—that depended upon his "free will." He was not responsible for making a better world, he couldn't if he wished to do so. (Mahatma Gandhi, who still lives in this outlook, told the writer personally that to speak of *making* a better world manifested a regrettable lack of humility.)

When, however, modern science began to bring rapid change into social life, the older doctrine that man could not effect changes in the world of affairs not only became intellectually untenable, but so untenable that a new outlook was called for to replace it. William James (*q.v.*) began then to talk about a "uni-

verse with the lid off" in place of the older "block universe," namely, a universe in which the future is not yet wholly fixed but man does help to create it as it comes. John Dewey (*q.v.*) made the general idea central in his philosophy and built thereon his social, ethical, and educational systems. On this outlook it is the duty of man to study his culture to reshape it better for human living, and education should so upbuild us all that we shall become increasingly active and effective in using thought creatively to make a better world. To find such an active and creative place for education it was necessary to displace the hindering doctrine of necessitarianism. W.H.K.

NEGATIVISM. Negativism is the tendency on the part of an individual to resist everything suggested or commanded. It is particularly common among pre-school children and seems to reach a climax about 2½ to 3 years, decreasing greatly after 5. In milder forms, however, it may persist through adolescence and even into adulthood. This form of behavior may be either of the withdrawal or aggressive type, and is found among individuals of all degrees of intelligence.

In small children negativism may be caused by the children's desire for attention, their wish to assert their independence, or their attempt to imitate adults who frequently say "no" to them. Negativism is often their way of expressing their growing awareness of themselves as personalities. In older children or adults negativism may be shown by refusals to comply with requests, attempts to escape unpleasant duties (withdrawal), and tendencies to pout and to be quarrelsome (aggressiveness).

Suggestions which seem to be helpful in dealing with negativism are to avoid nagging or arguing with the child, to phrase requests or commands so that compliance is assumed, or to ignore refusals and resistance wherever possible. If negativism is used as a defense against feelings of insecurity, discovery and

removal of the causes of such feelings are necessary before adjustment can be effected.

NEGLECTED CHILD—See **DEPENDENT CHILDREN**; **REJECTED CHILD**; **UNDERPRIVILEGED CHILDREN**.

NEGLIGENCE. Negligence is of significance because normally no one may be held personally liable to pay for the damages resulting from an accident unless those damages have been the result of his own negligence.

Negligence consists of the failure to act as a reasonably prudent and careful person would act under the given circumstances. Reasonable prudence is determined in light of the ability to gauge or foresee danger. If, under the given set of facts, a reasonably prudent person could anticipate danger, the failure to act so as to forestall such foreseeable accident is negligence. The crucial issue is not whether one did foresee, but whether the law says that the mythical creature known as "a reasonably prudent person" should have foreseen an accident.

For example, a teacher who leaves dangerous chemicals readily accessible to students, a school bus driver who fails to stop his bus when surrounded by a swarm of pupils, a school board that provides improperly constructed shop equipment, are all guilty of negligence, since a reasonably prudent person would have foreseen that the given facts might lead to injuries. But the mere occurrence of an accident is not of itself sufficient to brand a teacher as negligent. If in the exercise of reasonable prudence there would have been no cause to suspect danger, the mere occurrence of an injury does not raise actionable negligence against the teacher. So, for example, there is no negligence in permitting a student to water a plant in a school conservatory, nor in allowing a child outside of the school building to bounce a ball on the street, even though injuries do in fact result from such activities.

Since negligence is the failure to act as a

reasonable person would under the given circumstances, the specific circumstances, obviously, alter the acceptable mode of conduct. Providing a referee may be necessary for a competitive basketball game, but not for free-play activity. Clearly the scope of safety precautions must be greater in a vocational shop employing lathes and power-driven machinery than in a library. What would be reasonable to expect under some circumstances could not be reasonably foreseen under others.

Furthermore, the scope of one's duties condition the nature of his obligations. A principal has more extensive responsibilities than a classroom teacher, and might be held liable for an accident during a school dismissal while the teacher of the class involved would not be negligent, since the teacher's duties would under normal circumstances be restricted to her own class, whereas the principal would be expected to make provisions for the dismissal procedure of the entire school or for the administration of the safety patrol system.

While it is normally true that liability follows upon negligence, there are certain *legal defenses* which nullify the effect of negligence. *Contributory Negligence* consists of negligence in respect of one's own safety or protection; just as others must act towards us with reasonable prudence, so must we act with reasonable prudence in regards to ourselves. The failure so to act, known as contributory negligence, absolves an admittedly negligent party of liability for an injury to which the injured party's own negligence contributed; so, a child old enough to know better is contributorily negligent for picking up a red hot poker. Another defense is called *assumption of risk*, and denotes legal recognition of the fact that voluntary participation in certain activities assumes the normal risks attendant thereupon; so, the candidate for the football squad assumes the dangers, and cannot ascribe them to another's negligence, of ordinary bodily contact; and the spectator at a baseball game, the dangers of foul tips. A third *legal defense* is the doctrine of *vis major*, or Act of God, or uncontrollable act of the elements. Also in the nature of a defense is the doctrine of *proximate cause* which requires that the injury complained of must have some substantial connection or causal

relationship with the alleged negligence before the admittedly negligent person may be held liable for the injury in question. (See LIABILITY.) H.N.R.

NEGRO EDUCATION. The term *Negro education* has come to have general application to the problems incident to the education of the minority Negro race in segregated schools in the United States, and in colonial areas of European powers where Negroes live. The term is one of convenience, and it is unfortunate that the usage sometimes suggests the existence of essentially qualitative racial differences.

Negro education is co-extensive with the existence of schools enrolling only or principally Negroes. The area involved includes the seventeen states and the District of Columbia where the segregation of races in public schools is mandatory by law, in turn enforced by a public opinion founded in ancient traditional practices. There are also many segregated schools for Negroes in other states, principally in the eastern and middle-western states where the concentration of Negro populations within the last generation has resulted in public school segregation. Public demand for racial segregation in the schools appears to be a symptom of periods of racial maladjustment. In the pre-Civil War period, Negroes were generally excluded from public schools of all kinds in middle-western states; and they were educated at public expense only in separate schools in such states as New York and New Jersey. The extension of more liberal attitudes following the Civil War resulted in the admission of Negroes to the general public schools in most of the states of the North. Following the heavy migration of Negroes to northern urban areas after 1917, a considerable public opinion to segregate Negroes became manifest in those areas. In states where the laws forbid the principle of racial segregation in schools, the segregation of Negroes has been achieved by drawing school district lines to coincide with areas of segregated racial residence. To all practical intents and purposes, the elementary school Negro populations of many northern cities are as closely segregated from the elementary

white children as though they lived in Atlanta or New Orleans.

In addition to Negroes, other minority groups such as the Indians, Japanese, Chinese, "Mongolians," Moors, Eskimos, and Mexicans have been affected by segregating legislation, or custom, from time to time.

Of the 12,865,518 Negroes living in the United States in 1940, 9,904,619 lived in the Southern region, 2,790,193 in the North, and 170,706 in the West. Seventy-seven per cent of the race lived in areas of legalized segregated schools; perhaps the majority of the elementary school children in the North, and a large proportion of the high school educables were enrolled in schools which were, in fact, segregated schools.

The duplication of educational facilities for white and Negro children in the South, particularly, gives meaning to the term "Negro Education." Used at first for convenience, the term takes on new meaning as we understand more fully the complex differences in personality rooted in minority existence. The work of Allison Davis and Charles Johnson, and the recent investigations sponsored by the American Youth Commission have made a profound contribution to this enlarged understanding. Today when we speak of "Negro Education" we are thinking of a separate administrative structure, separated at the base but unified at the top in white administrators; but we think increasingly, also, in terms of a group of children and adults whose entire life is conditioned by circumstances peculiar to their existence as a racial minority. The American child is, in theory, to be educated for a world of equal opportunity; no limits are set upon his achievement. The same theory may apply to Negro children; but the necessity for realism in the face of the semi-caste status of the American Negro is much greater than that demanded for other American children and their schools.

In the light of this situation, *Negro Education* comes to mean the variety of realistic adjustments which must be made in educating—in separate schools—a group of children for whom the ordinary American principles guiding educational theory do not apply.

Standard tests when applied to a Negro population may be expected to show substandard achievement in terms of national

norms; a fact that may be explained either by basic racial incapacity, or by social and economic differentials. Vocational education may mean for the typical American school population an education in the skills and techniques requisite to initiation into the framework of American industry. For Negro children vocational education means the development of a program constantly shadowed by the knowledge that Negro students, as adults, will find entry into the industrial world difficult, if at all possible. School finance for the typical American population resolves itself into a problem of the electorate's deciding how much it will pay for the education of its children. For Negro children, the problem is immensely complicated by old attitudes hostile to extension of the education of Negroes, and by the fact that the Negro population of the schools is usually, in the South, a non-voting population.

The perspective of the record indicates great progress in the establishment of public institutions in which Negroes are being educated in the essential tools of the American culture. The percentage of Negro educables enrolled in elementary schools has, in the South, increased from practically nothing in 1870, to more than eighty-five per cent today. The considerable extension of educational opportunities reflected by this figure is shown also in the reduction of Negro illiteracy from a figure perhaps as high as 95 per cent at emancipation to less than fourteen per cent today. The scattered mission schools established by Northern philanthropy after 1865 have grown to comprehensive public school systems which, each year, reach larger numbers of children with much better equipped teachers and more satisfactory equipment. Secondary schools now enroll more than a quarter million Negroes; the percentage of Negroes 14-17 years of age enrolled in high schools is now approximately 25 per cent, five times as high as in 1920, although still hardly one-third of the figure among white educables.

The first Negro college graduate of record was John Russwurm, of the Bowdoin class of 1826. In 1922, according to Johnson, only 558 Negroes were graduated from colleges throughout the country with baccalaureate degrees; by 1936 the number was 2,108, and by 1942 in excess of 3,000. The small Negro

private colleges of a generation ago have been succeeded by better supported private foundations and state colleges with greatly increased facilities.

In the field of graduate instruction, Negroes must still get their advanced training in northern institutions, though a beginning has been made in the provision of graduate and professional education for Negroes. Particularly significant in its promise for the future is the cooperative enterprise in Atlanta, bringing together four undergraduate colleges in one organization, with a graduate school superimposed. While the segregated school as an institution has been upheld by the Supreme Court of the United States, the court has also held that where separate schools are maintained each state must provide *equal* facilities for study. (*Missouri ex rel. Gaines vs. Canada*, 305 U. S. 337, 59 S. Ct. (1938).)

In a sense, all of the problems connected with the education of Negroes in America are "special," in view of the unique status of the minority. The development and organization of curricula, the adequate training of teachers for the curricula to be used, the financing of the schools, and the administration and control of schools; each presents significant variations from what might normally be expected.

Curricula. This problem may best be illustrated, negatively, by the comment of a Mississippi legislator, when legislation regarding free text books was under consideration, that the Negro schools did not need to teach Civics, as the knowledge to be gained therefrom would be useless, and perhaps dangerous, for Negroes to acquire. There is further illustration in the historic controversy that raged thirty years ago among Negroes as between the Booker T. Washington (*q.v.*) "industrial education" school and the "talented tenth, liberal training" school represented by W. E. B. DuBois. In general this controversy may be said to have been resolved among Negroes, who recognize today that their greatest educational need is the provision of greater facilities of all kinds and on all levels. It is, however, still a question of moment among many white citizens and administrators. Negro schools of all sorts have derived their curricula from the formulations in vogue in schools in the American tradition; applied to the economically and socially sub-standard

NEGRO EDUCATION

Negro population, the result frequently is an even greater futility and inconsistency of formalized routine than exists in standard American schools. For example, the standard American curriculum may call for the use of textbooks about certain material, to be read at a certain rate per hour or day. A sub-standard, isolated white American rural population suffers marked disadvantages in adapting itself to this expectation. The sub-standard, isolated Negro American population, with only a very recent tradition of literacy, equipped with sub-standard reading skills, and devoid of the appropriate area of experience, finds itself even the more at an educational disadvantage.

As suggested above, much of the difficulty arises from the assumption that there is a standard American culture to which all children should, and do, have access; that there is a standard American school population; and that there is a standard American method by which educational processes may initiate all American children into the aforesaid American culture. The rapidly growing realization of the fallacies of such an argument, where Negro children in the mass are concerned, has already led to salutary beginnings of reform. The fact that teachers of Negro children are at least becoming aware of these difficulties is a great recent gain. In a sense, the problem is not primarily one only for Negroes; it is a problem of helping the entire American educational system become conscious of the wide gap between the theory of universal equalitarianism and the fact of individual, social, and economic differences so patent in our culture.

Finance. Children from a defective social and economic *milieu* need greater facilities to repair their initial handicaps than well-advantaged children and yet the whole history of American education reveals that we have consistently provided, in public and in private schools, better educational opportunities for the children with better initial advantages, and poorer opportunities for the handicapped child. This condition is aggravated where Negroes are concerned. As the American children farthest down in the economic scale, coming from the most illiterate stratum and the area of worst health habits and practices, they should logically require an extraordinary proportion of school

expenditures if true equalization of educational opportunity is to be achieved. In fact they receive extraordinarily low proportions of expenditures. This is true in the quasi-segregated systems of Northern cities as in legally segregated systems in the South. The differences may range from a State like Mississippi, where the annual per capita expenditures for Negro children are typically one-fifth those for white children, to a Northern city where per capita may appear to be more even, but where classrooms may be crowded, buildings antiquated, and inspired or sympathetic teaching absent. In the South the situation is complicated by the poverty of the section, and by the high proportion of educables—black and white—to adults and resources, as compared with other sections of the country. It is clear that there is no satisfactory solution to the problem of financing schools for both races in the South on an equitable basis, short of federal equalization.

Administration and Control. Negroes participate in the local administration of their schools as principals and supervisors, and occasionally hold state administrative positions. The Jeanes Supervisor, a county official originally made possible through the philanthropy of Miss Anna T. Jeanes, is now supported principally by local county funds. The supervisor serves generally as an Assistant County Superintendent for the Negro schools. It is generally believed among Negroes that the presence of members of the race on controlling boards would lead to more serious attention by those bodies to the needs of the Negro schools. H.M.B.

NEIGHBORHOOD SCHOOL — See ALL-DAY NEIGHBORHOOD SCHOOL.

NEPOTISM. Nepotism in its original sense referred to the practice of rulers and earlier popes of granting honors, dignities, offices, and the like to relatives, usually nephews. The meaning has been broadened to include similar practices followed by anyone in public office. Education is by no means free of nepotism. An investigation in one state revealed that almost one-third of the teachers employed had relatives connected with the school employing them. More than half of the states and many cities have passed laws and regulations to curb this practice. One of the most effective methods of controlling nepotism is to make provision for selecting teachers and superiors on a merit basis similar to that used by civil service bodies. (See TEACHERS, SELECTION OF.) J.E.G.

NERVE—See NERVOUS SYSTEM.

NERVOUS CHILD. There is no standard clear-cut definition of the term *nervous*, but it is generally used to describe behavior which is characterized by extreme activity, restlessness, anxiety, and irritability. This condition is found at all ages and at all levels of intelligence, and may vary from mild cases to those with advanced mental disorders.

The nervous child may exhibit a few or many of the following symptoms: overreaction to chance stimuli with many useless and diffused motor responses; squirming, fidgeting, and restlessness in sleep accompanied by dreaming or night terrors. He may show certain tics and mannerisms, fatigue easily, and have food dislikes. He is overenergetic (cannot relax), excitable, and tense; negativistic, irritable, and complaining. His emotions are easily aroused; he is oversensitive, extremely egocentric, and may show some specific, intense fears.

Nervousness may be due to the inheritance of a highly sensitive or poorly organized nervous system, or to glandular imbalance. The majority of cases, however, result from living in an atmosphere of excitement, anxiety, and insecurity. Usually, these children have unsolved personal problems and hence are in a constant state of emotional conflict. Their living habits are frequently not well regimented, e.g., insufficient sleep and irregular meals.

Because of wide variation in the causes and symptoms of nervousness, the treatment of each case is an individual matter. Some children are relieved by relaxation, massage, and the introduction of quiet, simple, wholesome living conditions, while others require medication or glandular treatment. The emotional aspects, however, are the most difficult to overcome. By removing the source of conflict with its accompanying tension, the neurotic child will be helped greatly. Parents and teachers often can ameliorate the situation by being calm; refraining from nagging and scolding about trivial things; not referring to the child's nervousness, especially in his presence; giving suggestions rather than commands; relieving him from too much pressure; and giving him a feeling of security. Special classes for nervous children do not exist in the public schools, because it is thought that their condition would be aggravated by imitating one another's behavior.

NERVOUS SYSTEM. The human nervous system is generally divided into the *cerebrospinal* and *autonomic* systems. The cerebrospinal system consists of the *brain*, or *encephalon*, lodged within the cranial cavity; the *spinal cord* lying in the vertebral column; and the *peripheral nerves* incoming from sense organs and outgoing to striped muscles, and covered by a special sheath called *myelin*. The autonomic system consists of clusters of nerve cells which lie outside, but mostly connect with, the brain and cord and innervate the heart, smooth muscles, and glands in the interior of the body. The main parts of the brain are the *brain-stem*, or the *medulla oblongata*; the *cerebellum*; and the *cerebrum*. The brain stem is the "lower center," or the "first connection" of the brain with the incoming and outgoing nerves of the heart, lungs, stomach, head, and face, just as the spinal cord is the "lower center" for the nerves of the arms, legs, and most of the trunk. The cerebellum has by all evidence much to do with the maintenance of bodily posture and equilibrium, but connects with peripheral nerves and thus with sense

organs and muscles only through the brain stem and spinal cord. The two most important portions of the cerebrum are the *cerebral cortex*, or simply the *cortex*, which is the gray matter of an estimated 14,000,000,000 nerve cells and immediate branchings forming the outer coating of the cerebral hemispheres, and the *interbrain*, or *diencephalon*, consisting of *thalamus*, *hypothalamus*, and *epithalamus*. The cortex is admittedly at the base of all our conscious experience and intelligence, while the interbrain presumably gives experience its vaguer groundwork and is claimed by many to play a significant role in feelings and emotions.

The autonomic nervous system differs from the cerebrospinal in that its nerves are not covered by myelin, and their conduction is about one-third as fast—roughly 40 meters as against 120 meters per second. It is seemingly a phylogenetically older system, and some of its sections appear to show even the primitive nonsynaptic (v. infra) nerve-net organization of the lowest invertebrates. It is, however, in the main subject to cerebral control, and the name "involuntary" often given to the organs it innervates should be construed in a relative sense. Not only may thought processes affect in some way heart beat, digestion, or kidney action, but even such local and ordinarily involuntary reflexes as the contraction of the pupil of the eye to an increase in illumination may be conditioned and thus somewhat brought under central supervision. There are two divisions in the autonomic system, the *sympathetic*, or *thoracic-lumbar*, lying in the middle of the body, and the *parasympathetic*, or *cranio-sacral*, centered in the upper and lower portions of the body. The two divisions respond differentially to a variety of drugs and their effect on behavior is mostly antagonistic. The first division, for instance, accelerates heartbeat, dilates the pupil of the eye, and inhibits digestive and genital action, while the second retards heartbeat, constricts the pupil, and stimulates digestive, excretory, and genital action. The fact that the organs innervated by the autonomic system are characteristically overactive or underactive during emotional states, together with the apparent correspondence between the antagonism of the sympathetic and parasympathetic divisions and the behavioral and experiential antagonisms in love and anger, fear and

appetite, mirth and grief, and general pleasure and displeasure, has singled out this system for special experimentation and has given rise to a good number of theories and speculations in neurology, psychology, and even philosophy.

The structural and functional unit of the nervous system is the *neuron*, consisting of a nerve cell as body and two kinds of special processes, the *dendrites* and the *axons*. Dendrites carry nerve impulses toward the cell body and are short and tree-like in appearance. Axons typically conduct the impulses away from the cell, are slender, and may reach a few feet in length. The usual term "nerve" refers to a bundle of axons, and "nerve fiber" to a single axon, the average diameter of which is approximately $\frac{1}{1000}$ of a millimeter. The impulse propagated along a nerve fiber and neuron in general is by all evidence electrochemical in nature, resembling the action in a galvanic cell, and, more specifically, the depolarization of a hydrogen film on a copper wire immersed in a concentrated acid solution. After a nerve fiber has been stimulated, a certain time has to elapse before it may be brought again into normal action. This is called the *refractory phase*, the duration of which is on the average about $\frac{1}{60}$ of a second. First there is an *absolute* refractory when the nerve fiber does not respond at all, then comes a *relative* refractory when the fiber reacts only to stronger than normal stimuli, and then there is a *supranormal* phase when weaker than normal stimuli may also set it off. At any particular time, however, a nerve fiber will either respond maximally or not respond at all; this is known as the "*All-Or-Nothing Law*." Stronger stimuli cause more repetitive discharges in the fibers and also arouse more fibers to action so that resulting muscular and glandular responses are greater in magnitude. The minute electrical charges generated by nerves in action are called *action currents* or *action potentials*. In recent years it has been found possible to obtain such currents directly from the surface of the intact head, and these are known as *brain waves* or *electroencephalograms*. Electroencephalograms are of several types, differing in frequency, amplitude, and general pattern, and the differences appear to correlate with such psychological activities as thinking, sleeping, and dreaming, and with

age, intelligence, mental disease, and even personality types. Their discovery is no doubt one of the most interesting advances in contemporary neuropsychology but many of the experimental claims are in need of further checking and verification.

While the neuron is the unit part of the nervous system proper, the *reflex* is the unit of the complete sensori-neuromotor act. A model reflex need consist only of (1) a *receptor* or *sense organ*, which may range from the simple free nerve endings for transmission of pain to the elaborate apparatus of the ear or eye, (2) a set of *sensory* or *afferent* neurons carrying impulses to the spinal cord, brain stem, or interbrain, (3) a set of *motor* or *efferent* neurons taking over the impulses from the sensory neurons and carrying them to (4) a set of muscle fibers or gland cells called *effectors*, and (4) *synapses*, which are in the nature of one-way valves between the sensory and motor neurons and the motor neurons and the effectors, and which make the impulses irreversible and, incidentally, slow them up. In actuality, one or more sets of central or *internuncial* neurons intervene between the sensory and motor neurons, as normally even a low-level and fast local reflex receives central stimulation while it is elicited. Reflexes and their parts, in general, interact with one another. Two or more reflexes may, for instance, be compounded to form a chain so that the response of the first reflex becomes a stimulus for the second, the response of the second a stimulus for the third, and so on. Or the compounding may be circular so that the response of the second reflex becomes a stimulus for the first reflex, even as the response of the first reflex is a stimulus for the second. Again, two or more sets of sensory neurons may deliver to a common set of motor neurons, or two or more sets of motor neurons may have a common set of sensory neurons, and an allied or antagonistic relationship may exist, or may be established through conditioning, between them. In all the known properties of reflexes do permit the postulation, upon their bases, of a complete system of integrated and coordinated behavior, and such systems have been offered by Russian reflexologists, a number of American behaviorists, and some noted psychologists and biologists. However, there has been in recent years so much emphasis upon holistic philos-

ophies, total organization, and individuation of parts from wholes rather than integration of wholes from parts that the view that the reflex is the *main* unit of behavior claims the support of only a portion of contemporary thinkers and scientists. Still, this does not mean that the reflex is not *one* of the main units of behavior.

Another aspect of neural action which is of general interest is that of brain localization. It has been said above that the cortex is at the base of conscious experience. Different portions, or lobes and areas, of the cortex clearly appear to deal with different modes of conscious experience. Thus, the hindmost portion of the cortex, the *occipital lobe*, governs visual experience. There is a primary visual area, the stimulation of which merely produces what might be called meaningless visual sensations such as bright and flickering lights, and a secondary area which gives rise to more meaningful phenomena such as the sight of different objects and persons. Injuries to the primary area results in blindness but lesions in the secondary area impair only the individual's ability to recognize objects, distinguish colors, read, and carry out other forms of visual perception. Below the occipital lobe and in front of it is the *temporal lobe* concerned with hearing. Above this lobe and further to the front is the *somæsthetic area* for experiences coming from the skin and muscle senses, and still further forward is the *motor area* dealing with single conscious movements of various part of the body and the *premotor area* controlling combinations of such movements. The large front portion of the cortex, the *frontal lobe*, apparently serves as a general combining and synthesizing center of all experience. However, while there is little doubt that there is a division of labor in the human brain, some complex activities may still be a function of the cortex as a whole, and there is evidence for alternate paths and vicarious functioning, when under certain circumstances one part of the brain may take over the duties of another injured part. There is also some truth to the popular statement that "one may have too much brain for his own good." Some clinical studies indicate that cutting off portions of the cortex may result actually in better adjustment.

Neural basis of learning. The attempt to determine the neural basis of learning has

led to much speculation and research. Unfortunately, however, while the general hypothesis that learning and memory leave some trace or change in the nervous system is seldom contested, there is as yet no direct empirical evidence on the specific nature of this trace or change. Speculations about exact neurosynaptic and neurocellular modifications in learning are becoming less fashionable, and about all that contemporary neuropsychologists feel justified in discussing is the general type of such changes. Three theories are current: First, the *specific pathway hypothesis*, which assumes that learning produces changes in specific neural pathways. This is the oldest and most commonly accepted view of the three, but one that does not do justice to the phenomena of functional equivalence of stimuli and responses which manifest learning in unactivated pathways and unpracticed muscles. Second the *general field theories*, favored by Gestalt psychologists, which consider learning to involve action at a distance and changes in the fields of force, presumably electrochemical in nature, of the entire nervous system. Such theories are extremely general and extremely difficult to verify experimentally. Third, the recent *reduplication theory* of Lashley, which postulates that the neural effects of learning are reduplicated in wave fashion, in large areas of the brain, and which to a large extent meets the objections to the first two theories. To be sure, all three theories lack specific evidence and their construction is more the result of a felt need than of a body of facts

NETHERLANDS, EDUCATION IN THE. The national organization of the system of education in the Netherlands dates from 1801 when a law was passed introducing a minimum program for elementary schools and qualifications for school teachers. The establishment of private schools was per-

mitted but these were not subsidized by the government. Higher education was restricted to the State Universities of Leyden, Utrecht, and Groningen.

The Constitution of 1848 required the government to provide elementary instruction in public schools for all, but did not require that this instruction should be compulsory or free of charge. Public elementary instruction was further regulated by the laws of 1857 and 1878. Strong opposition arose against this system of maintaining public schools at government expense without consideration for the possible preference of a substantial percentage of the taxpayers for denominational schools. The opposition caused the passing of the law of 1889 and the introduction of a special paragraph in the Constitution of 1917 by which equal rights to subsidies from public funds were given to private (practically always denominational) and public schools. These laws require the maintenance of public schools supported from the local community funds wherever desired and the allotment of equal sums (figured by the costs per pupil) to denominational schools which may be founded if a certain number of parents wish to do so and which must be supported as long as they have sufficient attendance and meet the requirements of the law. All schools are subjected to inspection by government appointed inspectors. Compulsory attendance of elementary schools for all children between the ages of seven and fourteen was introduced by the law of 1899.

Secondary instruction was organized by the law of 1864 which established the *Hoogere Burgerscholen* (High Schools). The curriculum of these H. B. Schools, however, is much broader and more extensive than that of American high schools. This type of school was founded primarily for boys and girls who were preparing for positions in business and clerical work. The main subjects are science and mathematics in addition to a thorough study of three foreign languages (French, German, and English). The H. B. Schools developed, however, into preparatory schools for students who intended to study science, medicine, or engineering in one of the institutions of higher learning. The law of 1876 transformed the old *Latin Schools* into *Gymnasia*, preparatory schools in which Latin, Greek, and History are the

main subjects and which give access to the Universities. The laws of 1909 and 1918 applied to secondary schools the principles valid for the establishment of denominational elementary schools.

One of the main differences between the Netherlands and American school systems is that the former leaves only limited opportunity to the students to select their subjects. The students of the secondary schools have no choice of subjects during the first years of the H. B. School and the first four years of the Gymnasium. After that they may choose between two different groups of subjects. The H. B. School *A* devotes more time to all subjects connected with business; the H. B. School *B* and Gymnasium *B* center around mathematics and the sciences, while the Gymnasium *A* devotes most of its time to humanistic studies.

In addition to the school types mentioned above there exist several vocational schools and schools for less gifted pupils. Only a few schools with a curriculum specially planned for girls have been founded. Most schools for girls follow exactly the same curriculum as the boys' schools. The requirements of the law prohibit any significant differentiation between boys' and girls' schools.

Sports and games have only a small place in all grades of the system of instruction. Here we must take into consideration the fact that the climate does not favor out-of-door games in the same way as in the U. S. Swimming, however, has been made compulsory in many schools, especially in Amsterdam.

The law of 1876 reorganized the institutions of higher learning, recognizing three State Universities and one City University, that of Amsterdam. For engineering the Technical School at Delft was founded in 1905, followed by the establishment of an Agricultural School at Wageningen in 1917 and two Business Schools at Rotterdam and Tilburg in 1913 and 1927. After the law of 1904 had opened the possibility of establishing privately endowed universities (without substantial contributions by the government), two denominational universities were founded. the *Free University* of Amsterdam, supported by the Reformed Church (founded in 1881 and recognized as a university in 1904) and the *Carolus Magnus University* of Nymegen

NETHERLANDS, EDUCATION IN THE

(founded in 1923), maintained by Roman Catholics. The university courses are on a level with graduate courses at American universities. Most subjects treated in the American colleges are dealt with in the H. B. Schools and Gymnasias.

Pedagogics have found many ardent students among the Netherlands teachers; nevertheless, few original theories of pedagogics have sprung up in the Netherlands. The eminently practical sense of the Netherlands induced them to apply, with moderation and a certain conservatism, the best of what foreign countries offered in this field. The prevailing idea that in education the personality of the teacher counts for more than all theoretical knowledge kept the Netherlands teachers from theorizing. To have set an example of how the teacher may educate his pupils by educating himself, has been the merit of the most prominent of the Netherlands pedagogues of the 20th century, Jan Ligthart.

The Netherlands contributed greatly to the development of learning in the United States, especially in the field of botany (Hugo de Vries) and astronomy, through the influence of Dutch scholars who migrated to the United States during the last quarter of the century. In the purely educational field, the relations between the two countries have been less close. An attempt to bring closer contact between the universities of the Netherlands and those of the United States was made in 1921 with the establishment of the Queen Wilhelmina Professorship at Columbia University, through the cooperation of the Netherlands Government, private promoters in the Netherlands, and Columbia University. This pro-

fessorship of history, language, and literature of the Netherlands has been entrusted to Professor A. J. Barnouw. Professor Barnouw succeeded in arranging a first exchange of students between the Universities of Leyden and Columbia, but the outbreak of the war in 1939 hindered further continuation of this first attempt.

Nearly 18 per cent of the public funds in the Netherlands was spent on education (1938). To this we must add several millions from private funds.

The government paid practically all expenses for education. Even the universities have only small endowments. State supervision over all types of schools is very strict. All final examinations of secondary schools and universities are controlled by State Commissaries. How severe their final examinations are appears from the following figures:

Of 1,498 candidates who presented themselves for the final examination of the Gymnasias in 1937, 210 or 14 per cent failed to pass.

Of 4,772 candidates for the final examinations in the H. B. Schools 762 or 15 per cent failed to pass.

Of 566 students in the Faculty of Law of all universities combined who came for the first examinations 377 passed, for the final examinations 350 passed out of 484.

In the Faculty of Medicine these figures were, for the three principal examinations; 555 and 382; 615 and 394; 430 and 322.

The following statistics give additional information and indicate the relative importance of private and public schools.

Statistics:

THE EXTENT OF ELEMENTARY AND SECONDARY EDUCATION

Types of Schools (figures of 1938*)	Number of Schools			Number of Pupils		
	Total	Public	Private	Total	Public	Private
Kindergarten	2,284	230	2,054	213,198	32,785	180,413
Elementary Schools	7,014	2,577	4,437	1,144,074	364,776	779,298
Special Elementary Schools	128	55	73	12,466	5,872	6,594
Total Elementary Ed.	9,426	2,862	6,564	1,369,738	403,433	966,305
H. B. Schools	136	91	45	31,954	21,325	10,629
Lycea**	56	11	45	15,301	2,993	12,308
Gymnasias	52	33	19	9,287	5,097	4,190
Vocational Schools	716			134,855		
Total Secondary Ed.	960	135	109	191,397	29,415	27,127
Grand Total	10,386	2,997	6,673	1,561,135	432,848	993,432

*Total number of inhabitants of the Netherlands in 1938: 8,727,321.

**The Lycea are a combination of H. B. Schools and Gymnasias. The figures indicate clearly that the public was much interested in this new type of secondary school and took it up while the government apparently did not care much for it.

Institutions of Higher Learning:

	Number of Students
University of Leyden	2,384
University of Utrecht	2,670
University of Groningen	921
University of Amsterdam	2,438
Free (Reformed) University	611
Roman Catholic University	446
Engineering School of Delft	1,838
Agricultural School of Wageningen	409
Business School of Rotterdam ...	566
Business School of Tilburg	222

Total University Students ... 12,505

Expenditures for Education from Public Funds: (1938)

For all types of schools:

From Community Funds, in guilders
(one guilder=0.52 dollars)

114,428,000 (out of a total of 776,418,000)

From State Funds

138,236 000 (out of a total of 714,190,000)

Total 252,664,000 (out of a total of 1,490,608,000)

NEURAL BASIS OF LEARNING—See NERVOUS SYSTEM.

NEUROSES (also called *psychoneuroses*).

This is the name given to functional disturbances, physical as well as mental, produced by emotional conflicts. Freud attributed a sexual origin to all neuroses, but a broader interpretation of their etiology is that they arise as a result of psychic conflict inherent in obtaining security and satisfactions in an environment or culture which is potentially threatening or dangerous. Symptomatic of the anxieties and fears developing from the mental conflict are the individual's compulsive acts, phobias, tics, hysterical paralyses, panic reactions, and somatic complaints. These symptoms may vary widely in their intensity and capacity to handicap the patient. The suffering they produce is real and not imaginary, the neurotically induced pain being as severe as that produced by organic or physical disturbances.

Neuroses differ from psychoses in that neuroses do not involve the total personality change, or produce the qualitative change in reality characteristic of psychoses.

Neurosis has been induced experimentally in both animals and children as a response to stress situations in which the individual feels

helpless through being confronted with a problem with which he cannot cope. As a result, he wavers between the desire to escape and the desire to solve the problem. Until a solution has been reached, he suffers from restlessness and tension; and, if the situation is prolonged, disorganization may ensue.

Although the fundamental structure of the personality has been set in the home by the time the child reaches school age—because it is to a great extent dependent upon the parent-child relationship—the teacher and the school environment can play an important role in either ameliorating existing emotional disturbances or reinforcing them. The overstrict home or the traditional schoolroom where restrictions abound is a typical environment for the development of neuroses in children. Furthermore, the inconsistencies of parents and teachers are often confusing to the child. For instance, a father may tell his child that to accept overcharge from a store is good business, while his mother may insist that it is stealing. His teacher, after urging him to show initiative and to be accurate, may reprimand him for being impolite if he criticizes or questions some of her statements. He is told to stand up for himself and not to allow others to pick on him, but he is also told that gentlemen do not fight. This usually creates conflict in the child's mind as to which course to pursue, with possible resulting neurotic symptoms.

Difficult as it may seem, however, the child must learn how to face the contradictions and inconsistencies in his environment. Nevertheless, the application of the principles of mental hygiene in home and school would reduce substantially the number of conflicts children meet. Until such re-education is effected, we shall continue to have many neurotic children who develop into maladjusted adults.

NEWSPAPER, SCHOOL—See PUBLICATIONS, SCHOOL.

NEWSPAPERS AND PERIODICALS, SCHOOL USE OF. Newspapers and periodicals have become a regular part of the collateral reading program in many social studies, science, English, and other classes. Recognizing the prominent part that such reading plays in our modern life, teachers are giving their pupils practical experience in reading, analyzing, and criticizing newspapers, news-magazines, and other periodicals. Several books guide the teacher in bringing accurate information to the pupils. On the high school and elementary school level Edgar Dale's *How To Read A Newspaper* (Scott, Foresman and Co., New York, 1941), has found much favor. Also usable on the high school level and excellent for teacher reference is George L. Bird and Frederick Merwin's *The Newspaper and Society* (Prentice-Hall, Inc., 1942). The *New York Times* issues a leaflet on newspaper reading and provides teachers with a manual and questions on the magazine section of the Sunday edition. Many local newspapers furnish sample copies for each member of the class studying a unit on the newspaper. Periodicals such as *Newsweek* furnish a teacher's manual for each issue. *Time* magazine supplies schools with current events tests covering the year's news. There are also several newspapers and magazines which are designed especially for school use. *Scholastic* magazine, *Current Events*, and similar periodicals are written especially for the school child. Other publications may be found for various grade levels.

One of the principal lessons which came out of the school use of newspapers and periodicals is that pupils must be taught to read critically. The analysis of propaganda has become an important activity in many schools. Pupils are urged to compare accounts of events in different newspapers, to check headlines against facts, to try to determine the editorial policies of various news-

papers and magazines, to use the newspaper index, to understand the sources of news, and to read further in order to obtain the necessary background for a better understanding of the events recorded. Thus, newspapers and magazines may vitalize school studies by illustrating current aspects of persistent problems in our history. They may be used to initiate the study of new problems and they may help to provide the pupil with an interesting and realistic fund of information. (See PUBLICATIONS, SCHOOL.) W.H.H.

NORMAL PROBABILITY CURVE.

When chance operates upon a large number of instances (for example, when ten perfectly balanced coins are tossed in the air thousands of times and the number of coins that fall heads up after each throw is counted), and the results are reduced to a frequency graph, this graph so often is found to approach a symmetrical, bell-shaped curve with a specific mathematical formula that it is called the *normal probability curve*, or simply the *normal curve*. There are many instances where psychological and educational measurements of a very large population also result in a curve which approximates closely that of the normal probability curve, for example, the curve representing the frequency distribution of the intelligence quotients of large numbers of unselected children.

Since the normal probability curve has a definite mathematical formula, there are many very useful functions which such a curve can serve. It is possible, for example, to measure the area in that section of the curve included between lines drawn perpendicular to the base line. It is also possible to measure the height of the curve at any given point

along the base line. These two procedures enable us, for example, to compute the number of cases that are included in that part of the curve between the mean and a line drawn one standard deviation below the mean. Similarly, it is possible to compute the point in the distribution above which are found a given number of cases or a certain proportion of the entire distribution. It is also possible to find the number of cases at any score value in the distribution, for example, the number of children who have a certain I.Q. These illustrations indicate only a few of the many ways in which the mathematical properties of the normal probability curve can be put to use. Tables which are reproduced in all standard textbooks in educational and psychological statistics make it convenient to use the area relationships of the normal curve without having to employ mathematics formulae.

Although there are few instances in which educational data can be represented accurately by the normal curve, there are many instances where the difference is so small that it is not unreasonable to treat the data as though they were represented by the normal curve. Let us assume, for example, that a standardized intelligence test has been administered to all the children in a school and that the arithmetic mean has been computed. If the entire school were retested, the arithmetic mean of the second distribution of scores could be computed. If the school were retested an infinite number of times, there could be computed an infinite number of arithmetic means. It would then be possible to draw the graph representing the distribution of the arithmetic means of the intelligence quotients of those children. There is reason to assume that this curve would have the same formula as that of the normal probability curve. It is therefore unnecessary to attempt the impossible task of endless retesting merely to determine how widely the mean of the intelligence quotients will vary. By using the formula for computing the standard deviation of the mean, the principal can soon find the limits within which the "true mean" is almost certain to be found. If the principal computed the mean I.Q. as 101 and the standard deviation of the mean as .05, he is safe, in assuming, as far as chance factors are concerned, that even if his pupils were retested with an equivalent form of the test,

the mean intelligence quotient for his school would not be above 102.5 or below 99.5, and he can assume further that the chances are roughly 2 to 1 that the mean intelligence quotient would be between 100.5 and 101.5.

This explanation of the normal curve and its properties has over-simplified the use of the curve and it has omitted many basic considerations that must be understood by all who would use the normal curve in statistical work. It does, however, lead to three significant conclusions. (1) The normal curve is at the basis of many of our measurements of reliability (*q.v.*); for reliability is only a measure of the consistency with which we should get the same results if the investigation were repeated endlessly with similar subjects and similar materials. (2) The normal curve, based as it is on the assumption of chance factors operating upon a large number of cases, should not be applied thoughtlessly to the relatively small numbers of cases usually included in educational studies. It is, for example, a gross misuse of the concept of the normal curve for the teacher to use it as a basis for predicting how many grades of A should be distributed in a class of thirty pupils. (3) The properties of the normal curve rest on a mathematical basis that must be understood before the properties of the normal curve may be applied to a specific situation. Though it is a relatively simple matter to learn to use the convenient tables of area relationships under the normal curve as they appear in statistics books, teachers and administrators should hesitate to use these tables unless they understand what the numbers represent, and the conditions under which the use of these tables is statistically and educationally sound. NORMAL SCHOOL. Historically, the normal school grew up in America to prepare teachers for the elementary schools, and despite changes its greatest emphasis is still in the elementary school field. Taking its characteristics from European examples and from American academies in the early nine-

teenth century, the normal school became a generally accepted institution of teacher education in America by 1900. Its greatest period of growth was prior to 1920, and since then it has gradually declined in number and importance as the teachers college (*q.v.*) took its place. Whereas there were more than 300 normal schools in 1900, there were only 50 or 60 by 1933. The word "normal" comes from the Latin via the French and originally meant a model or a rule, connoting that the object of the institution was to give teachers rules for teaching. The first normal schools in America were private schools appearing as early as the 1820's and 1830's. The first state normal school was established in 1839 at Lexington, Massachusetts. In the latter nineteenth century county normal schools, municipal normal schools, and high school normal schools made their appearance. By 1900 there were still slightly more private normal schools (including denominational schools) than there were public normal schools.

In the nineteenth century most normal schools admitted students directly from the elementary schools and even as late as 1900 the most common requirement for admission was only two years of high school work. The courses of study varied in length, two years being the most common, with the tendency in the last 50 years to increase the course to three or four years. In general most of the curriculum was devoted to a study and mastery of the elementary school subjects with additional work in philosophy, psychology, history of education, and observation and practice teaching. Although there was great variety in the courses taught, almost all normal schools included some sort of observation and practice teaching in a "model" school conducted either by the normal school or in the public schools.

Outstandingly influential normal schools prior to 1900 were at Oswego, New York, and at Worcester, Massachusetts. The New York State Normal College at Albany was an example of the trend after 1890 to extend the curriculum to four years, elevate the standards for graduation, and pay attention to the preparation of secondary school teachers as well as elementary. NORMS. The average scores, usually the medians, which have been made by large numbers of children to whom a standardized test has been administered and which are used as the basis for interpreting the achievement of students to whom the test has been or will be administered.

The raw score which a pupil obtains on a standardized test has little meaning unless his performance can be compared with that of other pupils. Since a standardized test (*q.v.*) can be administered and interpreted uniformly in many schools distributed over a large area, it is possible to compare the score earned by one student with the typical scores received by the great number of other children to whom the test has been administered. Such typical scores, or scores normal for groups, are called *norms*. The groups for which such norms are obtained are usually age or grade groups, occasionally subject groups (as chemistry students in the high school), even less commonly groups selected on the basis of social background or mental level. Practically all published standardized tests have *national norms*, that is, they have the average scores of students from all parts of the country who have taken the test. These may also be *local norms* which are based on the average scores of all students in a given state, county, city, or even school. The most widely used types of norms are *age norms*, *grade norms*, and *percentile norms*.

Age norms (*age equivalents*) represent the average scores obtained by groups of pupils who have been classified according to age. The raw score of 65 which a given child has received on a standardized test becomes more meaningful when the teacher, after consulting the table of age norms, learns that this was the average score received by children who were 12 years and 3 months old. Most of the early achievement tests, following the example of the intelligence tests, supplied a series of age norms, despite the many disadvantages associated with their use. Great difficulty is ordinarily encountered in obtaining standardization groups below elementary school age or above junior high school age.

It is difficult, too, to set age norms for very high or very low scores. Another important limitation in the use of age norms lies in the fact that the performance of a pupil who scores above or below the mean of his age is compared with that of a pupil who is either older or younger, as the case may be. This becomes increasingly important as the pupil's score deviates by larger amounts from the average score of his own age group. The major advantage in the use of age norms lies in the fact that they are easy to understand.

Grade norms (grade equivalents) represent the average scores obtained by groups of pupils who have been classified on the basis of school grade. Using grade norms, the teacher can tell that the score of 65 which one of his students has received was the average score on that test received by children who had been in the sixth grade for three months at the time they took the test. In general, the advantages and disadvantages of grade norms parallel those of age norms. A further limitation of grade norms develops from the lack of uniformity of school systems throughout the country. Grade norms which have been developed for eight-year elementary school systems are not applicable to elementary schools organized in terms of a seven-year sequence. It should be noted, too, that curricular content varies considerably in different school systems; what one school teaches in the fifth year another may teach in the sixth year while a third may omit it entirely, thus reducing the significance of the grade norms provided by a given test.

The *percentile norm* allows a different type of interpretation. Percentile norms state the per cent of pupils of a given age or grade level that are equalled or excelled by the given pupil. Thus, each individual is compared only with others of the age or grade group of which he is a member. With the aid of percentile norms, the teacher knows that the student's score of 65 on that test is a higher score than was earned by 72 per cent of the twelve-year-old children who have taken the test. The major disadvantage of percentile norms results from the unequal units used—the difference between the fifteenth and twentieth percentiles is rarely equal to the difference between the fifty-fifth and sixtieth percentiles.

The most important advantages of using

norms are that they provide a useful basis for interpreting the significance of a score and that they facilitate comparisons of scores earned by students at different times or in different schools.

There are, however, a number of serious drawbacks to the use of norms, especially to the indiscriminating use of norms by teachers who see them only as numbers published in tabular form. From the discussion above, it is obvious that the norm is nothing more than the average score received by large numbers of children. It reflects what these children have achieved and not what they can achieve or what they should achieve. Even when the average level of achievement is far lower than it should be, the teacher is likely to be satisfied if his students' scores are at the norm, or slightly above it. Moreover, norms are usually the results of widespread testing and reflect average achievement of large numbers of children, including those who have been taught by mediocre or incompetent teachers using outdated procedures and inadequate facilities. In this respect, local norms often give a better basis for interpreting scores than do national norms. By seeming to exalt mediocrity as a goal, the unwise use of norms may keep many schools or teachers from being more effective. A child's achievement should be interpreted in the light of what he can and should do and in terms of what the school is trying to help him to become; it is grossly inadequate to interpret his achievement solely on the basis of the average scores earned by large numbers of children who may be different from him in many significant respects. NORWAY, EDUCATION IN. From time immemorial the basis of Norwegian education has been the homes, and this is still so. Since the time of the Sagas, stories have been told and the culture and traditions of the country have been handed on to the children by permitting them to overhear discussions of civics, law, work conditions, and political matters. Parents also play a large

part in the administration and supervision of the schools.

History. Regular schools were founded in the Middle Ages by the Catholic Church for religious purposes. From about 1200 A.D. cathedral schools educated young men for the clergy. When the Lutheran State Church established confirmation, school laws (1739) were enacted providing for compulsory school attendance for all children to enable boys and girls to read the Bible. Illiteracy gradually disappeared. High schools were established in the cities while the cathedral schools, now controlled by the State, prepared for university studies. The free Norwegian Constitution (1814) put the power in the hands of the people, with the result that new school laws (1827), going beyond the religious purpose, were enacted. When full municipal self-government was introduced (1837) interest in good schools of different kinds increased sharply since they provided a basis for the people's full participation in political life. Teachers' colleges were established by the State Laws of 1860 which caused church supervision of public schools to be replaced by the direction of elected educational committees; compulsory school attendance was lengthened, and history, geography and sciences were introduced as subjects. When the parliamentary system was fully developed, new school laws (1889) established the *people's school* for the whole nation, governed by the people themselves. Better school buildings were provided, new subjects introduced, the period of school attendance again lengthened, the teachers' financial situation improved. The following years also saw great improvements in higher education. A State University was established in Oslo (1811) and since 1869 high schools and junior colleges have put the instruction of sciences and modern languages on an equal footing with classical instruction. The gradual emancipation of women opened high schools and colleges to girls, and, since the 1860's, gave them opportunity to be teachers. When the influence of the whole people again was increased through the growth of the Labor Party (Labor Government since 1935) new reforms brought great improvements to both primary and secondary education. This development was interrupted by the Nazi invasion (1940) which brought the quality of the education

to a severe test. Its superiority was clearly demonstrated, and the trials were turned into new inner growth.

Types of schools. a. The *primary school* is a State school supported by the local municipal authorities. It is compulsory for all children from the age of seven years. About 30 per cent of the children get no higher education. Nursery schools and kindergartens are not included in the systems; they are all private institutions and not numerous. Private primary schools are almost nonexistent; children from all different classes of the people go to the same schools. The "people's schools" consist of seven grades, the age of graduation is 14-15, and education is compulsory to this age. These schools work from 36-40 weeks per year with 18-33 hours per week. In 1935 they had 380,949 pupils, of whom 75 per cent went to rural schools. The number of children in one class is limited by law to 30. In rural schools more year-groups are often gathered, but the number is then correspondingly lowered, so that, e.g., in two-section schools the number of children in each room must not exceed 16. Illiteracy has been unknown for many generations. Besides instruction in the three R's the present schools teach religion, literature, composition, history, geography, sciences, zoology and botany, sewing and knitting, drawing, gymnastics, music; the boys are taught woodwork and carpentry, the girls advanced handicraft and cooking. Since 1939 English has been taught in the two highest grades in schools situated in the more densely populated areas.

b. *Secondary schools* all build on the foundation provided by the complete primary school. Most of them are under State or municipal direction. The more academic schools are the five-year *gymnas* and the three-year *modern school*. The *gymnas*, which prepare for graduation into the University, are divided into four branches, all giving training in Norwegian language and literature, foreign languages (English, German, and French), mathematics, biology and physical exercises, but each with a different emphasis: on Sciences, Latin, English, or Old Norse. More practical, but yet with general educational scope are the municipal *continuation schools* of one or two years, furnishing courses in bookkeeping, dress-making, trade survey, etc. The *youth schools* for students 16

NORWAY, EDUCATION IN

years and up, and the *folk high schools* for young people 18 or older provide general education without any examination, mainly to farm and labor youth. In most instances they are privately owned by organizations, but supported and supervised by the State. In addition to literature and history, emphasis is given to such subjects as civics, folk-music, handicraft. Being practically the only schools with dormitories they also offer informal training in community life and social relationships. General and special training was also provided through the numerous study circles organized by trade unions, political parties, associations, etc., and often supported by the State.

c. The *higher schools* continuing the education on the basis of one or the other of the secondary schools are *vocational schools*, including craftsmen's schools, technical schools, business schools and special schools for a number of trades: 33 agricultural schools, 56 schools for household work, 8 schools for small-holders, 5 dairy schools, 5 horticultural schools, 3 schools for forestry, a number of schools for navigation, schools for miners, fishermen, nurses, social workers, etc. The teachers in the primary schools were trained in ten teachers' colleges, most of them maintained by the State. Courses for graduates of secondary schools took four years; a two-year course was provided for graduates from *gymnas*. The students of the teachers' colleges came from all parts of the people, making the relationship between the grade schools and the people very intimate. The teachers' college often was the first step in a political, literary, or other career as well. Special colleges provided training for kindergarten teachers, teachers of gymnastics, drawing and art, home economics, teachers for small-holders' schools, etc.

d. The only *University* (Oslo) consists of five faculties: Letters, Sciences, Law and Economics, Medicine, and Theology. The length of study varies, but is usually five to seven years. An associated Pedagogic College gives extra training to teachers for *gymnas* and *modern schools*. A School of Pharmacy is associated with the Department of Medicine. A University in Bergen is planned and some teaching has begun. Of university standing are the Dental School (Oslo), the Technical Institute (Trondheim), the Veterinary

College (Oslo), the Agricultural College (Aas), the Teacher's Graduate School (Trondheim), the Commercial College (Bergen), the Creative Arts' School (Oslo), and the Military Academies (Oslo and Horten). These are all State-controlled institutions devoted to training and research.

e. For *deficient* children the state provided ten schools. The schools for the blind, deaf and crippled all provided for vocational training and were compulsory for children 8-21 years old. The schools for mentally deficient children were either special schools in the cities for fairly high-grade defectives in each community, or State institutions providing full care for defectives of all degrees. Norway also has ten boarding schools for neglected children and five reformatories for young delinquents.

Administration. The schools were governed in a thoroughly democratic way. Each primary school had a "visiting committee" consisting of parents elected for this task. The chairmen of all committees in a district were members of the school management committee chosen by the elected municipal council. This committee had the authority to make decisions concerning the primary and municipal secondary schools within the limits prescribed by laws and the financial support allotted by the local municipal council. Higher public schools had boards of trustees appointed by the Ministry of Education. The teachers and parents always had representatives on these committees and boards. The State and municipal administration encouraged personal initiative and experiments in the schools but demanded control in all cases. The school management committees were usually progressive; their proposals often have been the basis for governmental motions carried by Parliament and thus accepted as laws for the whole nation. The schools in Norway are interdependent, all belonging to a unified school system. Students have to go through one school in order to enter one that is more advanced. But there is also the possibility of transferring from one to another in corresponding stages.

Economy. The Norwegians have made great sacrifices for their schools. Education takes more than 10 per cent of the State budget and is the largest item on the budget of cities and counties. Elementary schools

are always free and so are the continuation schools, many youth schools, the technical schools, most trade schools, the University and similar institutions (with the exception of some laboratory and examination fees). In the academic secondary schools about two thirds of the students pay a nominal fee. Books, writing materials, etc., are usually furnished free in elementary schools, rarely in secondary schools. The elementary schools usually give all children free medical routine examinations and treatment, free dental care, often provide school baths and swimming pools, and in many places daily serve a substantial breakfast without charge (the *Oslo breakfast*). At the University a great number of students are given "study loans" for their living expenses, free of interest during the period of study. Dormitories are rarely found in connection with schools or colleges, the exceptions being the folk high schools, household schools, and a few rural *gymnas*.

Methods. During the last decades the activity school principle was encouraged. Progressive schools and classes were established. Direct methods in language teaching and personal experience in other subjects have been emphasized. The children were expected to work for themselves, to cooperate, to carry responsibilities, and to show initiative. All schools were coeducational. Laws of 1935 compelled each school of more than 12 pupils to have a library, and cooperation with public libraries was very efficient as well. The National Broadcasting System (controlled by the State) provided many good programs for the different grades. Lively cooperation was also offered by museums, theatres, and other cultural institutions. Intellectual regimentation was disapproved; each child was encouraged to work according to his capacities. The aims of the *people's school* was to bring up efficient, right-minded citizens and to develop the personality and potentialities of each individual child. The children were an important part of the Norwegian community and recognized as such. The tradition of a working, dynamic democracy was passed on to them. That this educational work was successful, was fully proved by the events during the Nazi occupation of the country.

During Nazi Invasion. Attempts were made by the Nazi officials to establish the "New Order" in the schools as early as the

winter of 1940-41. These were met by protests and strikes begun in February, 1942 when all teachers were ordered to teach Nazi theories and ideologies and all children 10-18 years old were instructed to join Nazi Youth organizations. Teachers, parents, and the clergy protested strongly and general strikes of teachers and clergy followed. Concentration camps, torture, deportation, and slave labor were the fate of thousands of striking teachers. The schools were closed for months at the time, the University stopped, and the students were sent out as lumbermen. But the spirit of teachers and pupils was stronger than brutal force, and no concessions were made to Nazi demands. Teachers who remain manage somehow to continue their classes in private homes—although strictly forbidden by the Nazis. The whole population, including even the children, are willing to risk their lives to keep Norwegian education and its traditions alive. A.G.S.

NOTEBOOKS. It is customary for teachers in secondary schools to require pupils to keep notebooks for various purposes in connection with the work of a class. With appropriate adjustments of content to the students' mental and educational maturity, notebooks are also used in the upper grades of the elementary school as well as in college.

The contents of students' notebooks vary considerably in nature and extent, and may include such items as assignments, class notes, outlines, directions for work, reading notes, references, maps, daily work, mimeographed or dittoed supplementary material, guide sheets, charts, drawings, and other illustrative material. Few schools have any uniform plans or regulations regarding notebooks. What the notebooks contain reflects the work done voluntarily by the pupils or that required by individual teachers. The teacher's failure to make good use of the notebook as a teaching device doubtless results in considerable loss in effective school work.

The types of notebook vary with the purposes for which they are kept. The loose-leaf type appears to be the one used most commonly because of its general utility and adaptability; the bound notebook has limited possibilities for organizing material and is apt to become a conglomeration of items. While personal preference and special uses are factors that should be considered in choosing a notebook for class use, the 8½ x 11 inches, letter size, stiff cover loose-leaf notebook, that can be opened and closed easily, is best for general high school and college use. The paper it contains is of good size for themes or reports and is well adapted for filing by teacher and pupils. Such sheets provide liberal margins for corrections or additions. There is room enough for adequate spacing of charts or diagrams, and for better organization of notes. Further, a notebook of this size can accommodate mimeographed or dittoed material of the size usually furnished by the instructor, as well as maps and other illustrative materials. By using dividers, the student can make one notebook serve for several classes, and when necessary such a notebook may serve as a convenient writing pad.

The values to be realized through the use of notebooks depend largely upon how well pupils have been taught to make use of them. Experienced teachers have found notebooks especially valuable in two respects. The proper use of notebooks helps develop habits of effective note-taking both in class and in study for reference use in class and for review, habits that are essential for effective school work and systematic learning. This use of the notebook implies training in both the form of notes and in the selection of impor-

tant items or points to be included. Second, the use of notebooks helps develop training in good work habits in studying, encourages neatness and accuracy in doing written work, and gives practice in planning the organization of materials for ready reference or other uses. The mere copying of teacher-made outlines or dictated material should be discouraged as an unjustified waste of time. The taking of voluminous notes or the gathering of excessive quantities of materials should also be discouraged. Teachers who realize that the notebook is an aid to learning and not an end in itself find little value in students' keeping elaborately decorated notebooks with fancy lettering, red underlining, and other decorative impedimenta which overburden the students out of all proportion to the educative value of the result. T.M.R.

NURSE, SCHOOL — See **HEALTH; SCHOOL HEALTH SERVICES; SOCIAL SERVICE ACTIVITIES IN SCHOOLS.**

NURSERY SCHOOL. A school for very young children (eighteen months to four years of age) is commonly called a nursery school. This is not to be confused with the day nursery, a much older institution, which is a social welfare agency established to give day care to the child of the working mother.

As its name implies the nursery school has characteristics of both the nursery and the school. Because the children are so young, many responsibilities, such as feeding, usually associated with the home nursery have to be assumed by the teacher in the nursery school. Nevertheless, the nursery school is more than a home nursery, for its teachers are trained in the field of early childhood education and its procedures are consciously planned in terms of the child's total development.

Before 1900, schools for children under five years of age were fairly numerous in the United States and in many European countries. In 1909 the nursery school as known today began in London with the establishment of the McMillan Nursery School, an institution with an educational program for children of the slums. Nursery schools achieved prestige when The English Education Act of 1918 recognized nursery schools as part of the public system.

In the early part of the twentieth century

NURSERY SCHOOL

there was widespread interest in child study, research, and educational experiment in the United States and as a result of this, nursery schools were placed in colleges as laboratories for research in growth and development. Departments of sociology and home economics maintained nursery schools so that their students could have opportunities for observation and practice. This laboratory type had such a large and varied professional staff that the nursery school gained the reputation of being an expensive venture. When it was accepted as a community service, it was seen that the nursery school could be developed on a more economical basis without lowering standards.

About 1924, nursery schools in the United States increased rapidly. Private schools made them a part of their program and philanthropic groups established them in congested parts of cities. Mothers in college towns and suburban areas started co-operatives, sharing expenses and services. The more progressive day nurseries inaugurated nursery school programs for the children in their institutions.

The first public nursery schools were established by the Federal government in 1933. These were work relief projects and were planned to give paid positions to unemployed teachers, nurses, dietitians, cooks, porters, and others. Although the funds were provided by the Federal government, schools were directly under local boards of education. Except for these work projects centers, the nursery school is still a private institution in the United States. However, there is a growing demand for publicly supported nursery schools, as evidenced by legislative bills appearing in various states and by the fact that some local school boards are considering the possibility of establishing nursery schools. War conditions have tended to focus attention upon the care and education of young children as a necessary step in both wartime and postwar planning.

While the nursery school is still in an experimental stage with a flexible program, which is being constantly modified as research reveals new findings, these factors are generally accepted as basic: a health program, adequate space and equipment suited to the age level, a parent education program, and trained personnel.

Because it is recognized that children of nursery school age are more susceptible to diseases than are older children, a definite health program is considered an essential part of the plan. This includes daily morning inspection of each child, isolation space, and a careful periodic check up. The workers, too, are usually required to present certificates of health.

Although some nursery schools have a morning program only, it is generally accepted that a plan that includes a noonday meal and a long nap is of value. This longer plan enables the teachers to recognize and handle difficulties that arise from resistance to food and sleep.

Movable equipment which furnishes opportunities for the children to push, pull, carry, and rearrange is considered necessary for physical growth and for experiences that tend to improve hand, eye, and muscle co-ordination. Care is taken to avoid the use of equipment that might cause eye strain. Large blocks, climbing apparatus, bicycles, wagons, doll carriages, runways, slides, and house-keeping toys are some of the satisfactory materials. A schedule providing opportunities to play with these things followed by a more quiet period, then more activity followed by rest is characteristic of a nursery school day. All periods are brief, as the child's interest span is short. Space in which to move about freely is requisite, and in many communities the minimum amount of space is determined by local boards of health.

Since the young child is so dependent upon home factors, close cooperation of home and school is of necessity a vital part of every nursery school program. This is carried out through individual teacher-parent conferences and reports, group study and discussion, and often through parent participation in the administration of the school.

While right physical conditions are important, it is universally recognized that the most important part of the school is the teacher. A nursery school teacher is expected to understand the implications of children's behavior at different age levels and under varying conditions, and is trained to recognize behavior that needs guidance. A college or university degree in the field of child development is considered essential for a nursery school teacher.

NURSERY SCHOOL

State teachers' colleges and private training schools are now preparing nursery school teachers through courses in child development, nursing, dietetics, parent education, psychology, mental hygiene and community resources. Degrees in this field usually qualify a student to teach in the nursery school, kindergarten or elementary grades. However, the trend is definitely away from separation of these three levels of teaching and the thinking is more in terms of early childhood education.

Although the interest in nursery schools is increasing, there is still a difference of opinion as to their value and need. One extreme group argues that the mother is the logical person to care for her children and that the young child should not be sent out of the home for care and education. At the other extreme are people who believe the child should be placed in a large social unit at a very early age and for as great a part of the day as possible. The first group often admits that the nursery school is advisable for children whose homes are broken, while the other sees the nursery school as a universal need and a state obligation.

Between these two extreme views is the be-

lief that the nursery school benefits almost all children and mothers. Those holding this opinion regard the nursery school as a help to the home through the parent education program, and advocate the nursery school because it relieves the emotional tensions that arise from too constant companionship of mother and child. They are aware, however, that there have not been enough studies yet to show the effect of grouping upon the very young child, and so they realize that it may be possible that the nursery school is too stimulating for some children. They emphasize the fact that the nursery school is never a substitute for the home, but has social and intellectual values that are supplementary.

OBJECT TEACHING. Jean-Jacques Rousseau (*q.v.*) in *Emile* stressed the need for presenting to his pupil real objects that they might be seen, handled, smelled, orientated, and put to use. Among those who became enthusiastic about the philosophy expounded by Rousseau was Johann Heinrich Pestalozzi (*q.v.*) who, in his *Book for Mothers*, took "sense impression" as his watchword and stressed the study of natural objects in place of words, and observation and investigation instead of mere memorizing. An American traveler, William C. Woodbridge, first brought the ideas of Pestalozzi to the attention of the American public in 1820, but it was not until 1859 that Edward A. Sheldon, inspired by an exhibit of models, objects, and methods-materials in Canada, succeeded in setting up, at Oswego, New York, a city normal school to train teachers in the object method of teaching. (See OSWEGO MOVEMENT.) Object teaching became somewhat of a fad in the 1870's and '80's. The movement left a vital impression upon American education. It changed classroom procedure from the old memoriter type of question and answer exercise to active class discussion, oral teaching, and demonstration.

Today object teaching is improved by better apparatus for demonstration and more readily available specimens. There has been a tendency to neglect the real in favor of representation of the real in the form of picture, slide, or motion picture. The better teachers are coming to realize that both the object and its representation have their place in the teaching process. The object possesses the advantage of producing a sense of reality and an appeal to the senses of taste, touch, sight, smell, and hearing. It is, of course, limited as to the size which can be made available. A picture or a model, such as that of a pyramid may be brought into the classroom

when the real object is unavailable. The object does not take the place of reading; properly used, object teaching should stimulate reading by creating a desire to know more about the object. In the broad sense, the concept of object teaching is embodied in current practice in the experience curriculum, (*q.v.*) commonly referred to as the Activity Program (*q.v.*). See SENSE TRAINING.)

OBJECTIVE TESTS AND EXAMINATIONS. Tests and examinations are said to be objective when all competent persons are in substantial agreement as to the answers. It must be recognized that objectivity is a relative term. At one end of the scale occur items which are fully objective, such as names, dates, formulas, mathematical computations, and the like. At the other end of the scale are located such discussion questions as "How can we best prevent wars?" and "What will the world be like in the year 2000?" It is probable that most concepts stressed in the elementary and secondary schools can be so worded as to be near the objective end of the scale.

The development of objective tests, often called *new-type examinations*, received a great impetus early in the present century as a result of several studies showing that the traditional essay examinations (*q.v.*) were highly unreliable. This unreliability, due in part to the limited sampling of the pupil's knowledge, resulted mainly from the subjectivity in marking the papers. It was found that not only will a group of teachers show wide disagreement among themselves as to the values assigned a given paper, but a second series of values assigned a group of papers by the

OBJECTIVE TESTS AND EXAMINATIONS

same teacher after an interval of time will disagree about as widely from his first series of values. In other words, the results showed clearly that teachers could neither agree with each other nor with themselves.

The objective examination appeared to be the obvious way out of the difficulty. Since the answers required were very brief, a much wider sampling of the pupil's achievement could be made in the time available for testing. Since the scoring was highly objective, it could be done quickly and accurately. Soon after 1920 such tests came to be used widely, enthusiastically, and often uncritically.

After a few years, however, discerning educators began to point out that objective tests afforded a sampling which was extensive in length but was likely to be extremely limited in depth. As commonly used, objective tests were restricted largely to the measurement of the pupil's memory for isolated factual knowledge. They touched but lightly upon understanding, judgment, and the ability to use knowledge in practical situations, and avoided altogether such intangible outcomes as attitudes, appreciations, interests, and ideals. The implication, however, that subjective tests do measure such traits is not justified. Recently, several promising developments have occurred which suggest strongly that these limitations are not necessarily inherent in objective tests but are due rather to insufficient skill in test construction. It is now generally recognized that any examination amateurishly made and used is almost certain to be a poor examination, and that poorly constructed objective tests are likely to be little if any better than the ordinary traditional examinations.

The value of any test depends upon the degree to which it satisfies three criteria; namely, *validity*, *reliability*, and *usability*. By *validity* is meant the extent to which the test actually measures what it is used to measure. In constructing or in selecting a test the teacher must consider what the specific objectives of instruction are for which measurement is sought, and then select the form of test that is most appropriate for this purpose. By *reliability* is meant the extent to which the test affords a consistent measurement. Two forms of the test, or two applications of the same test, must give essentially the same results. As a rule, the larger the test and the more objective the test, the greater will be its

reliability. By *usability* is meant the extent to which the test affords a measurement without unreasonable demands upon time, energy, or money. Most objective tests rank high in usability. The additional time required in preparing the tests is usually more than balanced by the greater economy in scoring the papers.

Objective tests are of two major types, *recall tests* and *recognition tests*. A recall test is one in which the pupil must supply from his past experience the correct response, rather than identify the correct response in a list supplied by the examiner, or judge the truth or falsity of a statement, as is done in recognition tests. Two common forms of recall tests are designated as *simple recall* and *completion tests*. It is difficult to make recall tests highly objective and at the same time avoid undue emphasis upon rote memory. In a *recognition test* the pupil indicates the truth or falsity of statements given, selects the correct response from several possibilities listed, or pairs related items arranged irregularly in two parallel columns. It is to be contrasted with the recall test in which the pupils must supply the correct responses from his own experience. Despite the fact that the scoring of recognition tests often involves correction for guessing (*q.v.*), it is usually more rapid and more completely objective than the scoring of recall tests. The most commonly used types of objective questions are:

Alternative-Response Test. A type of recognition test in which the student must choose the correct answer from two possible responses submitted. The commonest form of alternative-response test is the *true-false* (see below) type. Other common variations are *yes-no*, *same-opposite*, *right-wrong*, and *correct-incorrect*. In all such tests the factor of guessing (*q.v.*) operates at its maximum. In general, experimental studies have shown that alternative-response tests must be longer than other recognition tests in order to be equally reliable.

Analogies Test. In content, the analogies test involves the analogous, or parallel, relationship of two pairs of things, one number of the second pair to be supplied by the student. In form, the test may be either *completion* or *multiple-choice*.

OBJECTIVE TESTS AND EXAMINATIONS

Examples:

Complete the following proportions:

4 : 16 :: — : 81

white : black :: good : —

Write the number of the word that will complete the statement.

Tennessee is to Nashville as Georgia is to _____.

- (1) Atlanta (2) Athens (3) Augusta
(4) Macon (5) Savannah

The analogies test is fairly common in tests of intelligence, but its use in achievement tests is limited.

Antonym Test. Same as *opposites test*. (See below.)

Best-Answer Test. A best-answer test is a type of multiple-choice involving fine discrimination. The pupil must choose the best answer from a series of options more than one of which has merit.

Example:

Choose the clause that will best complete the sentence. Then, in the parenthesis at the left, copy the number that is before the correct clause.

- () Leguminous plants are important in agriculture because:
1. Bacteria associated with their roots return nitrogen to the soil.
 2. They will often grow on soil too poor to support other crops.
 3. The economic value of the hay crop is very large.
 4. They provide foods rich in minerals and vitamins.

Cause and Effect Test. Cause and effect tests are useful in the social sciences, as well as in the physical and biological sciences. Sometimes the multiple-choice form is employed, in which the student is required to select the correct cause (or the correct result) from those suggested:

Example:

Of these four events one is a result and the other three are causes which contributed to it. Underline the one which is a result.

Desire for gold, voyages of Columbus, conquest of Mexico, character of Cortez. Sometimes the matching form is used; the student is asked to associate each result or effect with its cause or antecedent.

Completion Test. The completion test is made up of sentences in which certain important words or short phrases have been

omitted. The sentences may be disconnected or they may be organized into one or more paragraphs. Each omission is indicated by a blank for the student to write in the correct form, or the blanks may be numbered to correspond to a column of answers at the side of the page.

Example:

Supply the missing word or words.

The intelligence quotient is obtained by dividing the _____ by the _____. Or, The intelligence quotient is obtained by dividing the -1- by the -2-.

1. _____
2. _____

Continuity Test. (See *rearrangement test* below.)

Disarranged Sentence Test. A test in which words listed in random order are to be rearranged so as to make sentences. Usually the words are rearranged mentally without being written down, the student merely indicating whether the rearranged sentence is true or false.

Example:

Rearrange each group of scrambled words into a sentence. If the resulting sentence is true, underline the word "true"; if it is false, underline the word "false."

grow and apples ground oranges

the intrue-false
true bought cannot friendship be.....true-false
fille est la frère son.....true-false

Identification Test. The identification test or exercise is accompanied by illustrations, usually in the form of maps, diagrams, or pictures, in which certain designated parts are to be identified or labeled. It is well adapted to measuring scientific information regarding the structure of plants, animals, and machines, as well as knowledge of map location in geography and history.

Matching Test. A test ordinarily consisting of two columns, the items in one column to be paired with those in the other column upon some basis suggested. It is a useful device for measuring the student's ability to associate events and dates, events and persons, events and places, rules, and examples, terms and definitions, causes and effects, and the like.

Example:

In which of the sources in the right-hand column would you look first to find the items

OBJECTIVE TESTS AND EXAMINATIONS

listed in the left-hand column? Put the number of the best source in the parenthesis before each item.

- () A discussion of the functions of Federal Reserve Banks
() An opinion on a current issue before Congress
() Gothic architecture
() A synonym for the word *exorcise*
() The source of the Orinoco River
1. Atlas
2. Economics Text-book
3. Editorial Page of *The New York Times*
4. Encyclopedia
5. Thesaurus

Mixed Relations Test. In this type of test the student is asked to indicate the one term in each series which is not consistent with the others. Sometimes used in achievement tests, the mixed relations test is more common in intelligence tests.

Example:

Cross out the word in each line that does not belong there.

Airplane automobile bicycle
 radio train
la nuit le chien l'après-midi
 le matin le jour

Multiple-Choice Test. A recognition test in which the student attempts to select the correct response from several options suggested. This is one of the most widely used of all test forms, and when carefully made is one of the best.

Example:

Within the parentheses, write the number of the word that best completes the sentence.

The amount of money earned each year by a savings account is called the 1. commission, 2. dividend, 3. interest, 4. premium, 5. profit ()

Opposites Test. An opposites test is a vocabulary test, usually in multiple-choice form, in which the student is to select the word in each list which is opposite in meaning to the first word given.

Example:

Select the word that is opposite in meaning to the first word given and place its number in the parenthesis.

Concave— (1) concrete, (2) complex, (3) complete, (4) convex ()

Rearrangement Test. A rearrangement test consists of a series of items in confused or random order to be rearranged in correct order according to a designated basis, such as chronological sequence, order of size, importance, etc.

Example:

Indicate by 1, 2, 3, 4, 5 the chronological order in which the following events occurred:

- () Purchase of Alaska
() Annexation of Texas
() Louisiana Purchase
() Lewis and Clark Expedition
() Annexation of the Philippines

Several schemes for scoring rearrangement tests have been suggested but all of them are rather involved.

Similarities Test. A similarities test is a test in which each item consists of two (or more) terms which are alike in some way, together with a list of other terms of which only one is similar to the first two (or more). The student must identify the terms which are similar.

Example:

In each question there are four words alike in some way. The first three are given. Find the fourth among the remaining numbered words, and write its number on the blank line.

() barley, oats, rye . . . (1) alfalfa, (2) clover, (3) cowpeas, (4) timothy, (5) wheat.

Simple Recall Test. A simple recall test usually consists of a series of direct questions to be answered by a word or phrase, or of specific directions to the pupil. Simple recall tests are well adapted to, and are widely used for, the measurement of factual knowledge and for problems involving mathematical computation.

Examples:

Fill in the correct answer.

What is the capital of Peru? _____

What is the area of a room 12 feet by 14 feet? _____

Substitution Test. A test in which certain symbols are substituted for others according to a code or key. Sometimes used as a measure of intelligence.

OBJECTIVES

True-False Test. An alternative-response test which consists of a series of statements to be marked either true or false. Such statements must be worded with particular care to avoid ambiguous interpretation or unwarranted language clues which are called specific determiners. True-false tests are usually corrected for guessing (*q.v.*).

Example:

Indicate whether each of the statements is true or false by underlining either **TRUE** or **FALSE**.

TRUE—FALSE The United States Senate consists of two senators from each state in the Union regardless of the size or population of the state.

TRUE—FALSE The Speaker of the House of Representatives is elected by the popular vote of the people.

OBJECTIVES. Conceptions of objectives vary necessarily with theories of education. The chief current issue is one involving differences both in philosophy (values and accordingly aims) and in psychological outlook,—whether objectives are to be conceived primarily as subjects to be learned or in terms of living to be desired and character being built.

Objectives which stress subjects are long established and widely held. For two thousand years most people—educators and laymen—have conceived the aims of education to be the handing down to the young in systematic fashion of the racial inheritance as formulated by scholars and written in books. Though content and procedure have changed greatly through the years, this conception is

still dominant. Note, for example, the curricula of most schools and the expectation of most laymen that the school's job is to teach subjects. With this conception go also the assumptions that education is to prepare for adult living and that, psychologically, learning is apprehending, memorizing, storing for future use. The subject matter emphasis was reinforced (from c. 1800) by the theory of formal discipline (*q.v.*). Reasoning in mathematics, it held, strengthens the reasoning faculty and accordingly ability to reason in everything. Similarly, discriminating in Latin strengthens the faculty of discrimination; and so on. Though psychologists have definitely abandoned this faculty psychology, secondary schools and colleges still adhere to its assumptions and stress the subjects assumed to teach reasoning, discrimination, and the like. Latterly Bobbitt's extensive work on objectives (c. 1922), with manifold lists of subject matter needed by adults, still stressed subject learnings though it also came closer to living.

Objectives of the second type put first stress on helping young people enrich their lives and build the kind of character needed to continue living happily and effectively. The supporting reasons are both philosophical (valuing people and their living above subjects) and psychological (conviction that ends which are meaningful and immediately challenging to pupils release greater dynamic). One strand in these objectives, then, aims at the present living of pupils—that it improve in quality, that it demonstrate wholesome attitudes toward self and others and life situations; that the pupils grow in insight, in discrimination, in ability to profit by what the race has learned, that they grow in the understandings and ability necessary to control their own destiny. A second strand concerns the pupil's relationship to the social group—that he build attitudes, techniques, understanding necessary for effective living in democratic group life—in his immediate group and also in the wider community. To realize these aims requires, obviously, much book knowledge and also, to insure continued reading, a love of books. But in addition it requires actual experiences in doing, managing, carrying on living effectively and satisfyingly.

But merely teacher-objectives do not suffice.

Since pupils must develop not as yes-men, but as purposeful beings, they too must set up aims really their own. Teachers, then, work to help these pupil-aims grow; to include deeper insight, longer and broader views, better utilization of the race culture. Teacher foresight and planning for pupil growth are thus essential. But pupil-aims and pupil-planning are also essential if pupils are, through the practice of initiative, creativeness, and self-direction, to develop adequate adult personalities. (See AIMS OF EDUCATION.) M.Y.O.

OCCUPATIONAL ADJUSTMENT — See OCCUPATIONAL INFORMATION; VOCATIONAL EDUCATION; VOCATIONAL GUIDANCE.

OCCUPATIONAL ANALYSIS. One of the first responsibilities that is faced by an instructor teaching a new trade or occupation is to determine what to teach. This involves making an inventory or analysis of the trade or occupation. Trade analysis for highly specialized workers performing single-skill jobs calls for inventories of only what is to be done—the specific operation concerned. For skilled crafts the analysis becomes more extensive.

The analysis is made by having an expert worker perform the job, one step at a time. The analyst who watches this performance should be an expert educator with a knowledge of the techniques of occupational analysis because we assume that the analysis is to be used for instructional purposes. Either personally, or with the aid of a stenographer, the analyst records each step by describing it in such a way that a learner can do the same operation by following the analysis. Such a description often specifies what the worker must do, and what he must know to do the job successfully as well as the tools and materials he must be able to use. The analysis should be tried out to test its accuracy and worth. This is done by placing the tools, materials, and analysis in the hands of several beginners who have not previously done the job, to see whether they can perform it by following the analysis. Extensive units of

work are divided into smaller parts. The information needed is often put in the form of *operation sheets*, *job sheets*, or *work sheets*, which serve as aids in teaching, but not as substitutes for the teacher. Thus job analyses serve as a basis for determining what should be taught, and when translated into instruction sheets, serve as aids in teaching.

Occupational analyses are also made for production purposes, or for purposes of making repairs, for the guidance, for example, of auto mechanics or aircraft mechanics. Sometimes the analyses are published in the form of trade annuals. (See also INSTRUCTION SHEETS.) F.T.S.

Federal Security Agency, Office of Education, *Bricklaying, An Analysis of the Trade of Bricklaying Together with Suggestive Courses of Training for Apprentices and Journeymen Workers*, Vocational Division Bulletin No. 208 (U. S. Government Printing Office, Washington, D. C., 1941).

OCCUPATIONAL INFORMATION. In vocational guidance, *occupational information* refers to facts concerning the importance of the vocation, entrance requirements, lines of and opportunities for promotion, health and accident hazards, compensation, and other working conditions that are usually met in specific vocations or related groups of vocations.

In vocational education or training, the term is used in a somewhat different sense. The worker is expected to have or to develop trade skills and trade information or knowledge—the latter is usually in the nature of trade theory or related technical knowledge which some people call trade or occupational information. In vocational education a mastery of occupational information contributes toward vocational proficiency.

Occupational information may be secured directly, through observation, study, and discussion; or indirectly, through newspapers, periodicals, books, and from still and motion pictures. In view of the fact that there are more than 500 groups of occupations, containing in all more than 25,000 different payroll jobs, it seems wise to give carefully planned instruction about the more common, representative, and socially useful occupations to youth before the latter must select occupational pursuits. Spaulding and others

have shown conclusively that young people leaving school greatly need information about occupations and employment conditions.

Perhaps the most effective way of giving occupational instruction is through carefully organized classes taught by specially prepared teachers. The best time to do this seems to be during the junior high school years, and in the senior high school, before the pupils elect vocational curricula or go to work. Separate courses for girls and for boys are recommended wherever the enrolment warrants. Male teachers are preferable to women, as a rule, for teaching occupational information to boys and to men; women teachers are probably better than men, as a rule, for teaching occupational information about homemaking, nursing and other occupations for which women have special fitness and interest.

Visual aids of many sorts, well organized textbooks, ample supplemental occupational literature, trips to places in which men and women work, and talks by persons intimately acquainted with occupational requirements and employment conditions help to make courses in "occupations" or in "occupational information" interesting and educative. (See VOCATIONAL GUIDANCE.)

OCCUPATIONAL STUDIES. Studies of occupations are undertaken to determine the extent and nature of the labor supply, the current and probable future labor demands, and the kinds and extent of vocational training that are needed or anticipated. Occupational studies or surveys are conducted under the auspices of boards of education and other local agencies, as well as by referral agencies such as the National Youth Administration and the federal and state employment services. In addition, classes in the study of occupations are often asked to make studies which serve educational purposes even though they seldom contribute much

to what is already known by more advanced students of occupations.

Occupational studies of a more general and more extensive sort are undertaken by such agencies as the American Youth Commission of the American Council on Education—studies such as that made by Howard M. Bell and his associates of the employment conditions in Maryland, and of attitudes of the young people between 16 and 25 years of age in that state. Other extensive occupational studies for different purposes are made by the United States Department of Labor, by the American Federation of Labor, by the Congress of Industrial Organizations, by manufacturers' associations, and by health, welfare, and other groups. Still other studies are undertaken by the United States Department of Commerce, Bureau of the Census, and by state and local groups desiring information about occupations or persons employed therein.

Schools and colleges make occupational studies to determine teaching content, or to determine placement opportunities for graduates. Certain occupational studies are of a relatively broad nature and are perhaps better called studies of industries. (See VOCATIONAL EDUCATION.)

OCCUPATIONAL TESTS. The term *occupational tests* is somewhat more inclusive than *trade tests* because not all occupations or vocations are trades. A skilled trade is an occupation that requires an apprenticeship or learning period of several years. Some occupations, however, are learned in a few days, weeks, or months.

Occupational tests are of three types: oral, written, and performance. Persons may be selected for an occupation on the basis of one or more tests, both general and vocational. These may include (1) intelligence

OFF-CAMPUS CLASS — ONE-ROOM SCHOOL

tests, (2) aptitude tests, and (3) ability or achievement tests and personality tests. Since more workers lose their jobs through faulty personality traits than through lack of occupational knowledge or skill, and since intelligence, special aptitudes such as mechanical, musical or artistic, are important in determining fitness for an occupation or calling, it is clear that reliable testing for occupational fitness should be comprehensive and not limited to an occupational performance test, an occupational information test, or both.

Occupational tests may be given to assist in determining occupational aptitude, interest, progress, or achievement. They are given by prospective employers, employees, schools, school boards (for hiring shop teachers and others). Very few occupational or trade performance tests are standardized, though many have considerable reliability and validity.

Occupational information tests may be given orally, but are best given in written form. Their purpose is to find out what the individual knows about the occupation. Occupational performance tests are designed to test the person's occupational skills including how he selects and uses his tools and materials, and how he goes about his work. A half or a whole day is often required to take a trade performance test.

OFFICE OF EDUCATION—See UNITED STATES OFFICE OF EDUCATION.

OFFICE PRACTICE. The increasing diversification of clerical activities in business offices made the establishment of office practice courses inevitable. The subject was introduced into secondary schools in the period beginning about 1930. It has two major purposes: (1) The integration of subject materials learned in commerce courses taken previously, and (2) the development of skills in the use of bookkeeping machines, duplicating machines, calculating and adding machines, filing devices, etc.

The subject is becoming increasingly popular and is being advocated by leaders in business education as a means of diverting stu-

dents from the traditional bookkeeping and stenographic programs. The subject is typically taught in the twelfth grade and on the post high school level. (See also BUSINESS EDUCATION.)

H.A.T.

OFFICE RECORD CARD — See RECORDS AND REPORTS.

OFFICIAL CLASS—See HOME ROOM.

OGIVE—See GRAPHIC METHODS; PERCENTILES.

OMNIBUS TEST. An *omnibus test* is one in which the items are arranged in one continuous series with one set of directions, rather than grouped into sections according to types or content. The omnibus form is not recommended for achievement tests but is sometimes used for intelligence tests. C.C.R.

ONE HUNDRED PER CENT PROMOTION—See PROMOTION.

ONE-ROOM SCHOOL. The *one-room school* and the *one-teacher school*, usually synonymous terms, refer to the school in which there is only one teacher for all of the pupils, regardless of their school grade. Although this type of school is most prevalent on the elementary school level in rural areas, it is not limited, however, to either the rural school or the elementary level.

In 1938 there were 121,178 one-room schools in the United States. During the period from 1924 to 1938 approximately 44,000 one-room schools were abandoned in the various states. The U. S. Office of Education reported in 1934 that there were in our nation probably more than 7,000 one-teacher schools with five or fewer pupils enrolled, and that approximately 1,000 of these very small schools were being operated with as few as one or two pupils.

The great number of one-teacher schools in the United States may be attributed in part to the early American philosophy that education is a local enterprise. This tradition, together with sparsity of population, dearth of wealth, lack of good roads and means of transportation in certain sections of the country, has made very difficult the consolidation of small school units into larger ones. (See CONSOLIDATION OF SCHOOLS and TRANSPORTATION OF PUPILS.)

Although it is generally conceded that the

disadvantages of the one-room school far outweigh its advantages, one should remember that the one-room school often is the only practicable type of school that certain isolated areas can maintain. It is generally an elementary school, and it does provide ready access for the very young and small children for whom attendance at the consolidated school would usually necessitate longer distances to walk or to be transported. The one-room school may also serve as a community center for families living nearby. It has been said, moreover, that the younger children learn much from hearing the recitations of older pupils who often serve as tutors for the younger ones.

Most studies have shown, however, that the one-room school is less efficient than the consolidated school. Generally the teachers in the small schools are not so well prepared, well paid, or well supervised as are their colleagues in the consolidated school. Buildings and equipment are poorer. Per capita costs are generally higher. Pupil attendance is below standard. Terms are often short, and the time the teacher may give each pupil or each pupil or each class is limited. (See **UNGRADED ROOM**.)

The trend in most states toward consolidation of smaller units is still moving forward in accelerated fashion. In areas where consolidation is not feasible, dormitory and outboarding schools are being tried. Correspondence lessons, itinerant teachers, and part-time schools are used in some sparsely settled countries, such as Western Canada and parts of Australia, and might prove feasible for similar areas of our own country. W.R.F.

ONLY CHILD. One who does not have and never did have a brother or sister. While there are no statistically reliable differences

between *only* and *other* children at any age level, a few different tendencies may be found. *Only* children are less likely than others to have infectious diseases. In studies made of personality characteristics between *only* and *other* children, there is little general agreement except that *oneliness* is a factor of little significance. *Only* children seem to be slightly less timid, less extroverted, less self-sufficient; and to have somewhat larger vocabularies, be a little more ambitious, unstable and irritable than other children. When *oneliness* is unaccompanied by pampering there are practically no differences between the groups. Most of the assumed undesirable characteristics of only children derive from generalizations made on unscientific bases.

M.S.Q.

OPEN-AIR SCHOOL. Various kinds of open-air schools have been provided for children of lowered vitality. In them may be found children who are malnourished and anemic, tubercular control and cardiac cases, and others whose resistance has been lowered by disease. Some of the classes are called "fresh-air" classes or "open-window" classes; others "outdoor" classes and "outdoor" schools. These classes are not merely schools in the open air; they provide a health program which would be desirable for all children.

The characteristic features of the open-air school are: (1) cool, fresh air in place of the overheated air found in many classrooms; (2) provision for sunbaths; (3) small class size; (4) adequate medical supervision; (5) a school day which includes rest periods and is planned to avoid fatigue; (6) methods of teaching and a curriculum conducive to mental health; (7) special health instruction; and (8) the provision of an adequate diet. Among the benefits most frequently claimed are the improvement of health and physical tone, gain in health knowledge, a liking for wholesome food, increased mental alertness, and improved scholarship.

There are trends toward open-window rooms instead of open-air schools and toward classrooms with circulating air heated to about 60°F. in place of the unheated open-air classroom. A recent comprehensive survey of the education of handicapped children in New York City recommends, among other things, the reexamination of the criteria for

OPEN-WINDOW CLASS — ORGANIC DISORDERS

determining malnutrition and the return of children with temporarily lowered vitality to the regular classroom, with provision for rest periods under supervision. The most important trend is toward making the essentials of the open-air program available to all children.

OPERATIONAL DEFINITION. An operational definition is a statement so made that it may be immediately translated into effective action. If curriculum objectives are defined operationally, it is possible to devise evaluation instruments or techniques with which to appraise them. Such statements of objectives are most often in terms of behavior expected of students in certain situation. The objective "To develop skill in typing" may be defined operationally as "To write 40 words a minute, with no more than two errors." The operational definition makes it possible to determine whether or not a student achieves the objective. See **EVALUATION**.)

V.E.

OPERATIVE TECHNIQUE—See **MORRISON PLAN**.

OPPORTUNITY CLASSES. The term *opportunity class* or *opportunity school* has been used to designate a class or a school administering to individual differences. It is one of a number of terms utilized in connection with the education of exceptional children. For the most part the term has been used to designate restoration, adjustment, or the coaching of classes or groups. In some school systems, however, it is used to designate ungraded classes, backward classes, or classes for exceptionally bright pupils.

The term has been used most widely in New York City, where classes designated as "Opportunity A-B-C-D Classes" have been organized. Their purpose is to develop a program that will provide individualized atten-

tion for pupils with behavior problems. The letters "A" "B" "C" and "D" are used to indicate the various age groups, as follows:

"A"—pupils with an average chronological age of less than ten years.

"B"—pupils with an average chronological age of less than eleven years.

"C"—pupils with an average chronological age of less than twelve years.

"D"—pupils with an average chronological age of less than thirteen years.

The Opportunity A-B-C-D Classes in New York City represent an opportunity to put into practice the adjustment point of view in dealing with the education of children.

In other situations entire schools have been designated as "opportunity schools." An outstanding example of such school is the Opportunity School of Denver, Colorado, which has had remarkable success in rehabilitating pupils. In this school pupils having behavior problems are brought together and a modified curriculum, designed to meet the needs of individual pupils, is placed in effect.

In other school situations "opportunity rooms" have been opened, in which pupils with either educational or behavior problems have the advantage of individual work and study with their teachers. Leading cities in the conduct of such work include Baltimore, Boston, Cleveland, Chicago, Detroit, Milwaukee, New York, Philadelphia, Pittsburgh, St. Louis, and San Francisco. ORGANIC DISORDERS.—Organic disorders or defects include all diseased conditions or injuries caused by some physical disturbance of the body. These may be mild or serious, chronic or temporary; and may affect one particular organ, or may be widespread. Some organic defects are obvious,

e. g., hare lip and cleft palate, blindness, deafness, loss of limbs, etc.; while others are less easily discovered, e. g., brain tumors, syphilitic infections, tuberculosis, glandular imbalance, etc. Although the present trend is away from making a clear-cut distinction between organic and functional conditions, the majority of physicians still make such a division; and feel that the diagnosis and treatment of organic disorders is primarily a medical problem. The present discussion, therefore, is restricted to the psychological accompaniment of organic disorders, and to only those which are not considered mentally abnormal.

Where accident or disease results in permanent physical handicaps or disabilities, the effect upon personality development may be far-reaching. In general, it is not the handicap in itself which affects personality, but the attitude which the person assumes toward his condition. This attitude, in turn, is influenced greatly by the social and cultural situations involved. Thus, in our society cross eyes might make a girl feel inferior, whereas in Turkey such a condition would not be serious.

In many instances the existence of organic defects may cause the individual to develop feelings of extreme anxiety, inferiority, and rejection. For example, a child with a weak heart may concentrate upon his disability to such a degree that he may feel unable to participate in any kind of activity, or even to mingle with other children. Mild physical disturbances are frequently used, also, as means for escaping responsibility; or as an excuse for absences from school.

In cases of serious physical disability an important problem is to determine what the individual actually can do, and then to give him encouragement and intelligent guidance by directing his attention to his assets rather than to his liabilities. It often may be possible for an individual to overcome his handicap by direct compensation, e. g., restoring weakened muscles to normality through exercise and massage. Where the handicap is irremediable, however, indirect compensation, through activities not impeded by the deprivation, offers the best means for adjustment. Thus, the deaf individual can excel in situations where concentration and good vision are essential. It is important, however, not

to carry either type of compensation to extremes, or a warped personality will result. A major factor in adjusting to physical handicaps is the attitude which society has toward such defects. Regardless of the person's success in compensating for organic disabilities, if others continue to misunderstand, pity, or scorn him, he cannot make satisfactory economic and social adjustments. (See MENTAL HYGIENE.)

ORIENTATION. Orientation in education implies adjustment and the development of perspective. Few special efforts were needed for it until about a generation ago when students began to come to high school and college in large numbers and from a variety of backgrounds, and the curriculum began to include a large number of courses. Today a freshman orientation program and orientation courses are common, not only in colleges throughout the country but in some secondary schools, where the same general features are prevalent as in colleges. Most colleges have "freshman week" in which upperclassmen and faculty members explain to freshmen the chief campus features, college and community religious and other organizations, and the college regulations; as well as advise and help them not only in registering for their courses of study but also in otherwise furthering their education. Some colleges maintain camps where an extended freshmen picnic is held to help make the orientation informal, pleasant, and effective. Tests of intelligence, of scholastic knowledge in several key fields, and of health are also usually given at this time so that the college, as well as the student, can have the necessary data regarding his relative abilities and scholastic attainments.

Orientation courses are of two kinds: those offering students general suggestions covering college study and life and those introducing various curriculum fields. The former are usually given little or no college credit; the latter are regular curriculum courses. The general suggestions are usually given in compulsory lectures for freshmen concerning the history of the college, the opportunities which

ORTHOPEDIC DEFECTIVES, EDUCATION OF

college provides, budgeting of time, and methods of study. The need for orientation courses in the curriculum fields has arisen with the increasing number and complexity of curriculum departments. Some of these latter orientation courses give students a bird's-eye view of a department of knowledge, being arranged primarily for students who can spend only a term or two studying the subject; thus, freshman mathematics today may introduce the student not only to college algebra, trigonometry, and analytic geometry but to calculus and differential equations as well. Other orientation courses introduce students to such groups of departments as the social studies, the humanities, the physical sciences, and the biological sciences. They may be either for students planning to specialize in these fields or for other students. In the last decade the "general college" movement has been accompanied by orientation courses which are non-departmental in nature. These attempt to educate the student to understand not a department or group of departments but such phases of living as civic affairs, personal associations, relations with the physical universe, appreciation of the arts and other leisure activities, and health care.

The need and general trends of orientation efforts are undisputed. Freshmen probably need more special guidance now than ever before because of the complex conditions facing them both in college and in their own lives. What kinds of test, courses, and informal guidance will be most adequate can probably not be foreseen in detail. The problems of orientation are those of encouraging the best educational aims and the best means of beginning their attainment in a complex, changing world.

M.G.F.

ORTHOPEDIC DEFECTIVES, EDUCATION OF. In the United States remarkable progress has been made in providing education for the crippled. As late as 1914, most of the education for the orthopedic was in four American cities. Now, however, recent national statistics, published in 1937, indicate that there are 301 city-school systems in the United States which report schools or classes for crippled children.

The types of organizations under which crippled children in the United States receive education are: (1) schools for crippled only; (2) schools for normal and crippled children; (3) schools for various types of handicapped; (4) schools or classes in residential institutions; (5) a single multigrade class in a school for normal children; (6) a unit or center of classes within a regular school for normal children; (7) a class in a convalescent home; (8) a class or classes in a hospital; (9) occasional cases of crippled children provided for under the regular educational organization.

The crippled are housed in various ways; most common are the one-floor building or cottage plan, the multi-story, old buildings remodeled, and rooms or units of school buildings planned for normal children. The advantages of the cottage plan are apparent. The whole school organization is on one floor, and it is quite easy for wheel-chairs to be moved from one part of the building to another, and for the children to go without assistance to any part of the school. The multi-story building is used in some centers, and is especially necessary where land values are high. It is necessarily compact and must be equipped with elevators and a sufficient number of operators, so that children may move at will from one floor to another. In many cities or small towns old public school buildings, or parts of buildings, have been remodeled for the use of orthopedic classes. Very adequate and excellent provision is often made in this way, and at moderate expense.

Regardless of the manner of housing, or the place in which the school is to be established, the principles of security and comfort should be kept in mind, and every opportunity for therapy and healthful development should be present.

The curriculum of the crippled child requires a good deal of consideration, and will of necessity vary according to the physical set-up of the school. Where crippled children are educated in public schools, the philosophy and methods used in teaching the crippled are usually similar to those which apply to the normal child. If there is a course of study for normal children, this is likely to be followed, with necessary modification, in the orthopedic classes.

The activity program (*q.v.*), in the hands

of a wise teacher, offers many ways of solving the problems which arise due to age range, variance in ability, the necessity for multigrade classes and interruptions in the schedule of the crippled child. Because of the necessity for individual attention and because of the advantages flexibility offers, progressive methods are extremely satisfactory in the orthopedic classroom.

Most orthopedic children need an enriched program, since many have had long periods of hospitalization, confinement at home, limited social experience, and little opportunity to observe the world in general. Still others come from underprivileged homes. It is the responsibility of the teacher to provide situations which will give the child enriched experiences not only in everyday living and in academic work, but also in the arts and the cultural heritage. A well-balanced curriculum also should make provision for recreation, guidance, and club work; if the school does not assist in these things, the average crippled child may have a narrow life. The planning of a schedule often proves to be a very complicated problem. Prolonged absences, individual variations within the group, necessary interruptions for medical examinations, physiotherapy, rest periods, brace fittings, and other special services call for an extremely flexible program, which, of course, is essential to the best interests of each individual child. Another problem which complicates curriculum planning is the fact that many children are over-age, and retarded in school. Therefore the social and mental ages, as well as the actual classroom achievement, must be carefully considered by teachers and administrators.

Few specific studies of the intelligence of orthopedic children have been made, but the limited investigation thus far indicates that the orthopedic child tends to score on the Binet Test slightly lower than the normal child. It is likely that many factors are responsible for this: there are certain groups of orthopedic children who are not physically able to compete on standardized tests.

While it is true that the current century has witnessed remarkable advances in the development of the program for the crippled, still the incompleting task remains a challenge to the future.

In considering the unsolved problem it is important to call attention to the fact that

first and fundamental to the success of future programs is the necessity for adequate means for discovering the crippled. Every orthopedic child in the United States should be registered for care, education, and treatment.

ORTHOPSYCHIATRY. Orthopsychiatry is a term identifying the integration of the four professions, psychiatry, pediatrics, psychology, and psychiatric social work, for the purpose of the study and treatment of disorders of behavior and personality. It is an outgrowth of the Mental Hygiene and Child Guidance movements. It is demonstrated in the functioning of the average child guidance clinic where the four disciplines, working co-operatively, make a more valuable integrated contribution than could be made individually. (See CHILD GUIDANCE CLINICS; MENTAL HYGIENE.)

M.S.Q.

OSWEGO MOVEMENT. An organized attempt was made in 1861 at the State Normal School at Oswego, New York, to introduce into the United States the more significant aspects of Pestalozzian ideas of educational practice. (See PESTALOZZI.) Like that of Comenius and Rousseau (*qq.v.*), Pestalozzi's thinking represented a break with the narrowly conceived educational concepts and practices of his times. The "father of manual training" believed that schools should prepare for life in the home rather than lead away from it, that manual labor is an important means of education, and that the use of objects, specimens, and models is indispensable in teaching.

Foremost among those who fostered the spread of Pestalozzianism in this country was Dr. Edward Austin Sheldon of the State Normal School, Oswego, New York. He was one of those men of idealism, courage, and strength who make an institution. He brought to Oswego Miss Margaret E. M. Jones of London, and Herman Krüsi, Jr., the son of one of Pestalozzi's most successful associates. These and others pioneered at Oswego, and were so successful that educators spoke of the educational influence radiating from there as the "Oswego Movement". Most popular was

OUTDOOR CLASS (SCHOOL) — OVERLEARNING

the concept and the practice of studying the natural object instead of merely reading about it; of encouraging free discussion rather than calling for robot-like reproduction of words in books. (See OBJECT TEACHING.) The object-lessons as taught at Oswego became the talk of educators far and wide though not all the comments were favorable. What Dr. Sheldon of Oswego, his associates, and followers have done to modernize the practice of elementary and, through the latter, of secondary education, will not soon be forgotten. In spite of numerous instances of the later formalization of miscellaneous fact teaching which aroused unfavorable criticism, the movement paved the way for more thorough training of teachers and for the vitalization and enrichment of teaching methods in elementary and secondary schools.

In recent years the State of New York has erected, as a part of the Oswego Normal School, one of the finest industrial arts teacher training units in the United States. F.T.S.

OUTDOOR CLASS (SCHOOL)—See OPEN AIR SCHOOL.

OVERCOMPENSATION—See COMPENSATION.

OVERGROWN CHILD. The term *overgrown* may be applied to a child whose height or weight markedly exceeds the norm for his chronological age. Such conditions may be caused either by temporary or permanent glandular imbalance or by faulty diet; or it may arise from hereditary factors or from a very wholesome and adequate diet. The mere fact that a child is taller or heavier than are other children of his age may have little emotional significance; in fact his superiority in these respects may be an important asset in his adjustment both as a child and as an adult. It has been found, for example, that leadership among children is often associated with superior physical development. Surprisingly enough, the overgrown child may also find that his height and weight may affect his emotional adjustment adversely. The child who is heavier than his classmates may be the subject of ridicule and may even be unable to participate in the usual games played by children of his age. The overgrown child may appear to be much older than he really is and may be expected to have the mental ability of the child of the age level at which

he appears to be rather than that of a child of his own age. As a result, an overgrown child of average or even slightly superior mentality may be regarded by others as being below average in mental ability. In child society, any youngster who is different from the other children may find that his difference may be either an asset or a liability. Whether the child's greater height or weight improves or retards his emotional adjustment depends largely on the way in which this trait is regarded by his friends and by himself. This attitude, in turn, depends on the attitudes of parents and teachers. (See MENTAL HYGIENE.) R.V.M.

OVERLEARNING. To the psychologist, *learning* means the ability to make one correct reproduction of the fact or skill that is being studied; once a fact or a skill has been learned any subsequent repetition of it constitutes *overlearning*. Thus, the first time a child does a division example correctly he has *learned* division and the first time the child changes *he don't* to *he doesn't* he has *learned* to say *he doesn't*. The teacher is usually more concerned with overlearning than is the psychologist, for the teacher knows that the mere fact that a youngster has made the correct association once does not assure lasting understanding or skill. While the teacher is interested in the psychological problems of learning, he is no less concerned with the problems of overlearning. Overlearning need not be wasteful; indeed, effective overlearning is essential if permanence of improvement is to be effected.

The motivation of overlearning is often as difficult as, if not more difficult than, the motivation of learning. The pupil who sees the necessity for finding the area of the schoolyard may see no reason for doing all the other examples in computing the areas of rectangular plots. Mere repetition of the same type of situation, such as dominated the old-fashioned drill period, is usually so boring that little gain is made in encouraging retention. The modern teacher seeks constantly to discover learning situations that provide for overlearning in a meaningful setting. Thus the class that is charged with the responsibility of conducting the school bank may get so much practice in the fundamental operations in arithmetic that more formal drill is superfluous. (See DRILL; LEARNING; REVIEW.) B.B.F.

P

PALESTINE, EDUCATION IN. Palestine's unique position as the homeland of two peoples, the Jewish and the Arabic, accounts for its dual system of national education. The Department of Education of Palestine classifies all of the country's schools into these two categories in accordance with the two chief media of instruction, Arabic and Hebrew. Thus the 178 Moslem and the 195 Christian schools, maintained during 1939-40 by religious bodies of both faiths, are included in the Arab system along with the 402 "Arab Public System (Government) Schools." The 320 Jewish schools that are not under the control of the Executive Education Committee of the *Va'ad Leumi* (the Hebrew Nation Committee composed of the Jewish people's representatives), and the 419 Zionist schools comprise the "Hebrew Public System (*Va'ad Leumi*) Schools."

All of the schools, both of the Arab and Jewish systems, operate under the supervision of the Department of Education of Palestine, which inspects schools, distributes grants-in-aid, collects information about education, conducts and supervises examinations, and administers and maintains out of public funds the "Arab Public System (Government) Schools." In the third term of the school year 1939-40, this system consisted of 399 government elementary schools, with 49,722 pupils in elementary classes, 1,744 children in kindergarten classes, and 923 students in 33 secondary classes attached to 14 of the elementary schools. The 178 Moslem schools maintained in 1939-40 reported an enrollment of 14,204 pupils of whom 2,386 were girls. Three of these schools had secondary classes. A number of these schools were comparable with the government elementary schools, but the majority of them, according to the official report of the Palestine Department of Education, were "old-fashioned and inefficient." Of the 195 Christian schools reporting to the government in 1939-40, 119 were Catholic, 34 Protestant, 28 Orthodox, and 14 miscellaneous. The last category includes some

schools operated by the Society of Friends of the United States. The schools enrolled a total of 25,274 pupils, as follows: Catholic 15,700; Protestant 4,919; Orthodox 3,635; Miscellaneous 1,020. Some of the schools controlled by foreign missionaries were closed at the outbreak of the second World War; others, like the Italian, however, were permitted to continue with teachers from friendly nationalities and with lay teachers, if they taught Arab children and their buildings were not occupied for other government purposes.

The schools of the "Hebrew Public System (*Va'ad Leumi*) Schools" fall into three main divisions according to the country's major Zionist parties, the *Mizrachi* or orthodox religious group, the *Histadruth* or labor group, and the general Zionists. Each division enjoys considerable autonomy in the selection of teachers and the course of study, and in internal affairs. It emphasizes in its schools those things it deems most important, for example, the *Mizrachi* schools emphasize traditional Jewish life and studies; the Labor schools stress work as an element in education and labor as a factor in social organization; and the general Zionists, Jewish culture. In 1939-40, the 419 schools in this classification registered 56,900 pupils as follows: general Zionist, 176 schools with 32,279 pupils; *Mizrachi*, 82 schools with 13,860 pupils; Labor, 161 schools with 10,805 pupils. Of these, 195 were kindergarten schools, registering 7,860 pupils; 190 were elementary schools, registering 41,160 pupils; 19 were secondary schools registering 6,142 pupils; 6 were teacher training colleges registering 847 students; and 9 were technical, vocational and agricultural institutions registering 891 students. The other 320 Jewish schools enrolled 25,701 pupils, as follows: under private control—280 schools registering 17,808 pupils; operated by the *Agudath Israel Organization* (extreme orthodox group)—22 schools with a registration of 2,461; operated by the *Alliance Israelite Universelle*

(founded in 1860)—9 schools with an enrollment of 4,413; operated by the *Women's International Zionist Organization*—8 schools registering 616 pupils; and 1 (Evelina de Rothschild Girls' School) operated by the Anglo-Jewish Association (founded in 1871), with an enrollment of 616. In 1931, the Palestine Department of Education reported that about half of the Jewish private schools were the *Chedarim* (literally *rooms*, i.e., one-room schools generally held in the teacher's home), *Talmud Torahs* (Hebrew schools, i.e., where the Torah is taught), and *Yeshivoth* (Talmudical Academies). These emphasize the Jewish or "sacred" studies and except for the Talmud Torah do not offer instruction in the general or "secular" studies (arithmetic, though, is a frequent exception). Also, their medium of instruction is not always Hebrew. In the *Cheder* (singular of *Chedarim*) the medium of instruction may be Yiddish, Arabic, or Ladino, and in the *Talmud Torahs* and *Yeshivoth* it is generally Yiddish.

As already pointed out, the "Arab Public System (Government) Schools" are maintained, and the "Hebrew Public System (*Va'ad Leumi*) Schools" are assisted financially by the government. In 1939-40 the government's net expenditure for these purposes was £P215,076 for Arab education and £P50,793 for Jewish education. Apportionment of these moneys is based on the ratio of school age population (ages 5 to 15). This arrangement satisfies neither the Jews nor the Arabs. The Jews are dissatisfied because the plan takes into consideration neither the Jewish expenses for and achievements in education, nor the total days of attendance for all pupils, a frequently-used basis for the equitable distribution of school funds. The Arabs are displeased because the government's schools do not approximate the Jewish educational standards, and because they (the Arabs) do not control the government's Department of Education. The fact, moreover, that the total expenditure for education amounts only to between five per cent and six per cent of the government's budget, less than in most countries—even in those that finance an army and navy—is an additional cause for discontent among both peoples. The consequence is that education in Palestine is not compulsory and is by no means universal. The extent of education

varies considerably among the various religious communities. Thus in the Jewish and Christian communities almost 100 per cent of the children are believed to receive education of some kind or other, though much of it is of little value and the period of schooling may be short. In the Moslem community the extent of education is less. The approximate percentages of Moslem children who receive some education have been estimated at 80 per cent and 50 per cent for boys and girls respectively in towns, and 50 per cent and 4 per cent for boys and girls respectively in villages (Annual Report 1939-40, p. 2). In September, 1940, 56 per cent of the applications for admissions to government schools in towns and 42 per cent of the applications for admission to government schools in villages were deferred. The average period of elementary schooling in these government schools was about six years in towns and about four to five years in villages. "The majority of children do not proceed beyond the lower elementary cycle, a self-contained unit of five classes in towns and four in villages" (Ibid. p. 4). There exist a few hostels for some of the villages (and their number is small) who attend town schools, "but in general villagers attending town schools are badly lodged under their own arrangement" (Ibid.).

Schooling for the Arabs consists generally of instruction in the common branches and some manual work and/or instruction in the elements of agriculture. A "Government Arab College" and a "Women's Training College" in Jerusalem, and a "Women's Rural Teachers' Training Centre" in Ramaleh, with two-, four-, and three-year courses respectively, are also maintained by the government for the training of teachers for the Arab schools. In 1940 the total registration in these schools was below 150. They are really secondary schools with some work in pedagogy included in the curriculum as an integral part of the vocational instruction provided. The programs of the Jewish, missionary, and private schools, on the other hand, seek to duplicate in content as well as in organization the more advanced European or American educational systems. Accordingly, they do not as a rule, include agricultural or manual work in the elementary classes, which are devoted exclusively to instruction in the fundamental processes, and their secondary schools re-

semble very closely the secondary schools of the lands from which their founders or sponsors came. Thus the increasing immigration of refugees from Germany and Austria brought with it the establishment of a number of private *Gymnasias* and *Realschulen*, while the growing participation and influence of American Jewry in the Zionist Movement and in Palestine have assured a prominent place in the educational system for the eight-year elementary school followed by the four-year secondary school. Like the secondary schools after which they are modeled, these secondary schools primarily provide more advanced general education and aim to prepare the recipients for the "Va'ad Leumi Secondary School Leaving Examination," the government's "Palestine Matriculation Examination," the Hebrew University entrance examination, or the foreign examinations (i.e., London University Examination) administered in Palestine. They do differ, however, from their European and American counterparts in that they frequently include departments of agriculture at the elective level. The government, incidentally, also examines applicants for school certificates, diplomas in higher studies, and Arab teachers' certificates, and conducts language tests for candidates for government employment.

Most of the Palestine-educated teachers for the Jewish schools are trained in four Teachers Institutes, two for men and two for women. One of each is maintained by the *Mizrachi* in Jerusalem, and the other two by the general Zionists—the one for men in *Beth Ha-kerem* and the one for women in *Tel Aviv*. The *Mizrachi* Teachers Institutes offer a five-year course, and the Teachers Institute at *Tel Aviv* a six-year course, based on eight years of elementary school work. Only the two-year course in the Teachers Institute at *Beth Ha-kerem* is based on secondary school graduation. The trend, despite tradition Oriental antagonism thereto, has been toward more women teachers—"in the direction of the American situation," as some Palestinian educators fearfully put it.

Vocational instruction is also provided by the "Government Trade School" which the government maintains at Haifa for Arabs; the "Hebrew Technical Institute," also at Haifa, which offers training in architecture and in civil, mechanical, and electrical engineering to about 500 students; the two

Kadoorie agricultural schools, one for Arabs and the other for Jews, established by and maintained in part from the bequest of a wealthy oriental Jew of that name; and a number of special agricultural institutions.

The government of Palestine provides four scholarships for Arabs in British Universities and colleges, and two are provided by the British Council. In 1925, the Jews opened the Hebrew University in Jerusalem. Originally started as a research institution, which was already at work in some fields, the university assumed also the teaching function with the addition of a Faculty of Humanities in 1928. To date, it has conferred 405 degrees—374 master's and 31 doctor's in the arts and sciences. Its program includes instruction and research in Oriental and Jewish studies, the humanities, education, agriculture, mathematics and physics, the biological studies, archæology, and medicine. The Hebrew University also conducts a program of adult education, which, along with the other many facilities for adult education conducted by the Jews, is responsible for a wide program of adult education in Palestine. Similar facilities for adult education are maintained neither by the Arabs nor by the government, nor have the Arabs taken great advantage of the opportunities offered by the university. The university's student body has in recent years included a number of students from the United States, while 65 students from Palestine were reported to be in American universities and colleges in 1942. J.I.H.

PANEL DISCUSSION. The development of group discussion work in recent years as an educational process has led to the increased use of the panel method. Commonly, a panel, or team of instructors, will sit with a class and contribute to the discussion under the leadership of a chairman. In some instances panels include students as well as teachers, while some consist only of students. Panel discussions may be used in some classes throughout a year or a semester of work, or they may be an occasional arrangement used for special purposes.

The advantage of panel discussion is that a variety of points of view can be expressed by persons who hold divergent positions and who, therefore, can stimulate more vital and lively discussions among teachers and students. Moreover, a greater amount of student participation can thus be elicited, both in the class discussion and in the planning of the work for the group.

Limitations arise when the discussion is not carefully planned by the panel members, and rambles to such an extent that points are not clinched and summaries are not made. Unless the panel works together effectively both before and during the meeting to see that the discussion does not merely raise problems but leads to some profitable end, the students are apt to become bewildered. Panel work is criticized also because it is more expensive in faculty time and energy than the usual class system where many students can be handled by one instructor. When the panel method has been used effectively, however, the method is usually judged valuable and worth the effort. (See DISCUSSION METHOD.)

R.F.B.

PARAGUAY, EDUCATION IN. Paraguay is a centralized republic, one of the two land-locked nations of the Western Hemisphere. The backbone of the population is the *mestizo* who sprang from the early association of the Spanish conquerors with the *Guaraní* Indian women. However, periodical streams of immigrants of Spanish, Italian, German, and Central European origin have

brought in fresh European blood within the last sixty years. Racially the Paraguayans have a high degree of homogeneity and, in general, their appearance is European. The proportion of pure Indians (mostly confined within some far away forests) is negligible, probably no more than 3,000 in all.

The economy of the country is pastoral and agricultural. The most important export commodities are quebracho extract, cotton, packed meat, hides and skins, tobacco, timber, petit-grain oil, oranges, and yerba mate or Paraguayan tea.

The people are bilingual. They speak Spanish and *Guaraní*, the latter being the language of the aborigines who populated the eastern section of the country when the Spanish conquerors arrived in the first half of the sixteenth century. The official language is Spanish, but the *Guaraní* tongue, although not taught in the schools, is used everywhere, but more so in the rural communities than in the towns. Thus Paraguay offers the only example in the American continent of an Indian tongue that has survived its own native race.

Educational beginnings. The real organization of public education in Paraguay started in the middle of the nineteenth century under the administration of President Carlos Antonio López. In 1857 President López reported that there were 408 elementary schools with a total enrollment of 16,755. Under the same administration the first institution of secondary teaching, the *Academia Literaria*, was founded, and the corner stones for a law school were laid.

After the devastating war of the Triple Alliance (a coalition of Argentina, Brazil, and Uruguay against Paraguay, 1865-70), public education was reorganized within obvious limitations, but it has made substantial strides ever since.

Administration and Organization. The Ministry of Justice, Worship, and Public Instruction (*Ministerio de Justicia, Culto e Instrucción Pública*) administers public education. Only agricultural education, administered by the Ministry of Agriculture, and the School of Arts and Crafts (*Escuela de Artes y Oficios*), controlled by the Ministry of War and Navy, fall outside the sphere of influence of the Ministry of Public Instruction.

The body in charge of elementary and

normal education is the National Council of Education, consisting of the General Director of the Schools, who acts as chairman, and four councilors, all appointed by the President of the Republic. This body appoints and organizes the personnel of the elementary schools, draws up programs for the courses of study, regulates the functioning of the schools, and orients the trend of teaching.

Elementary public schools, operating day and night, are of three kinds: lower, intermediate, and upper. The first is rural and the other two are urban. In the normal schools elementary teaching is also carried on. For this reason the normal schools have two departments, one for the normal courses, and one where the teacher-students practice the art of teaching.

Children younger than six years of age attend the kindergartens; those in the cities and towns between seven and fourteen attend the regular day schools; those in the country communities between nine and fourteen attend the lower schools and those of fourteen, most of whom are employed, attend the night schools.

The period of elementary education is six years in the upper schools, five years in the intermediate, and three years in the lower schools. Having completed the six years of education in an upper school, the student may enter secondary school.

Secondary education is provided by the National Colleges (*Colegios Nacionales*), the first of which was founded in 1877 after the War of the Triple Alliance, and served as the basis for the future National University.

A Governing Board of Secondary Education (*Consejo Directivo de Segunda Enseñanza*) supervises and controls teaching in the secondary fields. In addition to the National Colleges, this board has charge of the commercial and professional schools, the latter being administered through special officials called Inspectors.

Curriculum and methods. In elementary education two curricula are provided, one for the rural and another for the urban population. But both are so intertwined that the students from the lower schools can continue their education in the intermediate ones. According to Professor Cardozo, "the trend of teaching is definitely practical; in the rural schools as well as in the urban the

active method is applied." The teaching is based on the ideas of Ferrière, Kerschensteiner (*q.v.*), Dewey (*q.v.*), Washburne, and James (*q.v.*). "Without disregarding intellectual, emotional, and vocational culture, great emphasis is stressed on manual training. In the rural schools the land is tilled, animals are raised, and national raw materials are industrialized." Politically, the trend of teaching is nationalistic and pacifist. No religious teaching is provided in the public schools.

The curriculum of the lower (rural) schools includes the following subjects: reading, writing, arithmetic, language, literary excerpts, practical knowledge, farming knowledge (agriculture, stock-raising, and manual training), singing and music, and physical training. School is held three hours daily.

In the intermediate elementary schools the same program is followed with the addition of geometry, geography, history, physics, chemistry, civic and moral knowledge, natural sciences, and drawing. School is held three hours and fifteen minutes daily.

In the upper elementary schools a complementary course with the same subjects is offered, with the exception of literary excerpts and farming knowledge. Three and one-half hours of study are conducted during the day.

There are 93 private schools, usually providing both primary and secondary education, and the more important are part time or full time boarding schools. These private schools offer in general the official standard curricula, and the courses of study are recognized by the official schools.

Secondary teaching is a regular stage through which all those students aspiring to any of the liberal professions provided by the University must pass. Before entering any University school it is necessary to have the diploma of Bachelor in Sciences and Letters granted by the National Colleges. Secondary education endeavors to give the student a general scientific and literary culture. The period of secondary education lasts six years with a total of thirty hours work per week. The complete curriculum of the six years of work includes the following subjects (in alphabetic order): algebra (two years); anatomy and physiology (one year); arithmetic, practical and analytical, (two

PARAGUAY, EDUCATION IN

years); botany (one year); chemistry (two years); civic instruction (one year); common law (one year); cosmography (one year); drawing, including penmanship (three years); economics (one year); foreign language, elective, either French or English (six years, including one year devoted to the literature of the selected language); geography (four years); geometry (two years); history (six years); hygiene (one year); Latin (four years); Latin and Greek roots (one year); logic (one year); mineralogy and geology (one year); philosophy and ethics (one year); physics (one year); practical ethics (one year); psychology (one year); Spanish (six years, including rhetoric, and history of Spanish and Latin American literature); trigonometry (one year); and zoology and biology (one year). Gymnastics is compulsory every year.

Special schools. In addition to the schools mentioned above, there are others that deserve mention. There are many professional schools for women, privately run but supervised by the State, which give young women professional training in dress making, manual training, home economics, typing, shorthand, mechanical embroidery, and secretarial studies. The *Ateneo Paraguayo* (Paraguayan Atheneum), an institution subsidized by the state, is in charge of artistic education. The subjects offered are music, painting, dancing, singing, interior decorating, foreign languages, and forensics. There is also a normal school of music. The Ministry of War and Navy operates a School of Arts and Crafts which trains students to be carpenters, blacksmiths, plumbers, shoemakers, tailors, mechanics, electricians, etc.

Agricultural education is provided by the *Mariscal Estigarribia National School of Agriculture* and various regional schools of agriculture. The National School aims at the formation of substantial groups of agricultural technicians with adequate scientific and practical preparation to guide national agriculture. The regional schools seek the preparation of farmers of a superior type to the present standard farmer of Paraguay, who is indeed very backward in his technical preparation. The agricultural schools also conduct research work on the different rural problems of the country in general and of individual

regions in particular, with a view toward improving the technical, social, sanitary, and intellectual level of the peasant.

The National University of Asuncion. The law governing the present University organization (enacted 1929) provides that University teaching will aim at "scientific research, professional preparation, and University extension." However, only the second of these three goals (i.e., professional preparation), appears to have real attraction for the students; therefore the University consists of a series of schools for liberal professions rather than anything else. The scarcity of funds also contributes toward this restriction.

The government of the University is in the hands of a Rector and a Superior University Council. Every school (*facultad*) has a Dean assisted by a Directive Council. The Rector is appointed by the President of the Republic from a panel of three candidates submitted by the Superior University Council, whose membership, for this occasion only, is increased by delegates from the student body of each school. The Deans, too, are appointed by the President from another panel submitted by each of the Directive Councils from among its members. The Minister of Public Instruction is an honorary member of the Superior University Council, without a vote. Yet the Minister may have all the power of the different governing officials or bodies of the University in case of intervention decreed by the Executive. The Superior Council consists of the Rector and the Deans of the schools. The Directive Councils of the Schools are formed by five professors and one student each, elected in general assembly of professors and students, respectively.

The National University, as well as the other branches of public education, must struggle against great financial limitations. Paraguay's population is thinner per square mile than that of any other American republic, and its economic productivity is necessarily weak. Under these circumstances what Paraguay is doing for the education of its people may be considered an achievement, though, when compared with the standard education provided by other richer countries, Paraguay's education leaves much to be desired.

Statistics. *Educational budget:* The na-

tional budget for 1942-43 is the equivalent of \$5,693,050, of which \$666,972, or 8.45%, is assigned to public education, divided as follows: elementary education, 65.63%; secondary education 10.14%; university education, 19.83%; agricultural education, 2.72%; scholarships and subsidies 1.6%.

Illiteracy: According to the latest estimate provided by the Director General of the Schools, the proportion of illiterates in the country does not exceed twenty per cent of the population. Some 40,000 children could not attend school in 1942 for the lack of building accommodations.

Enrollment:

	Students		Teachers	
	Boys	Girls	Men	Women
Elementary schools				
Public	92,948	75,707	414	3,063
Private	4,292	4,016	93	218
	97,240	79,723	507	3,281
Secondary schools	Students		Teachers	
Private	1,004		172	
Public	979		156	
	1,983		328	

The enrollment in the National University at Asunción is as follows: School of Law and Social Sciences, 335; School of Medicine, 365; School of Mathematics and Physical Sciences, 116; School of Dentistry, 168; School of Economics, 150; School of Chemistry and Pharmacy, 148.

(Most of the statistical data for 1942 used in the above survey is not yet available in published form. It was gathered for the writer by Dr. Adolfo V. Latasa in the different governmental branches in Asunción.)

PARENT-TEACHERS ASSOCIATIONS—See HOME AND SCHOOL COOPERATION.

PARENTAL EDUCATION. Any form of education whose primary aim is to help parents deal more effectively and more understandingly with their children. In the earlier stages of the parental education movement, parental education consisted almost exclusively in the study by parents of child care and child development. Since 1930, however, an important shift has occurred which is commonly described by saying that parental education has become "parent-centered" as well as "child-centered". This shift has been due partly to the discovery that parents' own emotional difficulties prevent good relationships with their children and often interfere with their own assimilation of information and advice, and partly to the growing recognition that "parents are people" and that it is better for everyone concerned if families are not permitted to revolve exclusively around the children. The need for parents to achieve security in all their relationships and to develop their own personal interests has recently been much emphasized. This means that it is often difficult to determine an exact boundary-line between "parental education" and "education for family life" (See FAMILY LIFE, EDUCATION FOR), or between "parental education" and adult education in general.

Organized education for parents was initiated in the late nineteenth century by mothers who joined together in informal groups to pool their experience and to seek out such guidance as was then available. Out of such informal groups came the Child Study Association of America, and the National Congress of Parents and Teachers (*q.v.*) both of which make important contributions to present-day parent education. Rapid changes in social conditions increased parents' desire for guidance, and professional individuals and agencies in quickly increasing numbers began to supply it. Parental education programs acquired public as well as private financial support; and fathers participated in the movement more and more, though never

PARENTAL SCHOOL

to the same extent as mothers. Today, parental education programs are carried on as a major or minor activity by a wide variety of agencies. These include Federal, state, and local departments of education; home economics, public health, mental hygiene, etc.; university extension and graduate schools; nursery schools; parent-teacher organizations and parents' organizations (See HOME AND SCHOOL COOPERATION); libraries; churches of all denominations; social agencies; and consultation centers. Books and periodical material designed for parents are increasingly numerous. Several centers for research in child development and the training of professional workers in parent education, such as the Iowa Child Welfare Research Station of the University of Iowa, have been established, chiefly since 1920. In 1925, the National Council of Parent Education, comprising agencies professionally engaged in parent education, was organized.

Parental education may be directed to groups or to individuals; most programs make use of both approaches. Group teaching is carried on partly by radio broadcasts and correspondence courses, but largely by lectures and study groups, the latter being increasingly popular because of the opportunity they provide for general participation. Subjects for study vary to some extent with the interests, economic level, and educational background of the groups. Universal problems like "discipline", "sex instruction", etc., are often selected for study discussion; it is also common for study groups to be organized around the problems peculiar to children of a particular age range. Study groups differ widely in several respects: the extent to which the leader dominates the group, the degree to which a plan or outline is adhered to, the use made of assigned and unassigned reading, the child-centered or parent-centered philosophy of the leaders, etc. In 1936, it was estimated that leadership in parent study groups was about evenly divided between professional leaders, engaged in parent education as a career for which they have specifically prepared, and lay leaders, members of the parent group who regard parent education as an avocation and who have received much less intensive training than the professionals. In addition to the fact that it makes possible a much wider extension of parent education

programs than could be carried out by professionals alone, lay leadership is thought to have certain positive values: it may allow more freedom of discussion within the study group than sometimes prevails in the presence of an "expert"; it may develop able leaders within a given community; and it may strengthen the democratic character of the parent education movement.

Individual instruction of parents in the form of sympathetic listening and guidance is provided by persons with many different professional backgrounds; study group leaders (in contacts outside of the group meetings); teachers and school directors, particularly of nursery schools, where directed observation of the children by parents supplements individual conferences; physicians and nurses; ministers; social workers; juvenile court and probation officers; etc. Child guidance clinics (*q.v.*) and family consultation centers (see FAMILY LIFE, EDUCATION FOR) are able to offer parental guidance of a much more thorough and therapeutic nature, through the services of psychiatrists and psychologists. The need for training parent education workers to discriminate between problems which they are equipped to handle and those which they are not is strongly emphasized at present.

PARENTAL SCHOOL. The parental school is a type of correctional institution which is an offshoot of the large public school system. The spirit and organization of these institutions are essentially like those of a school rather than of the old-type reformatory. The modern trend is toward individual adjustment with an early return to society rather than permanent institutionalization.

Whether the parental school has a place in a modern school system is a question to which no universally accepted answer can be given. The opponents of the parental school see in

it an unwelcome reminder of the attitude that regards misconduct as an offense to be punished rather than as a symptom of the child's maladjustment, which needs help rather than punishment. The institutional life at a parental school is so different from the child's life at home and in school, that many educators feel that commitment to such an institution does not result in the child's permanent adjustment to normal living conditions. For example, the stigma of such an experience may give him both the feeling and reputation of incorrigibility which, in itself, will make his readjustment more difficult. Although these critics of the parental school realize that some children present so many treatment problems that readjustment can be carried on more effectively if he is removed from his family, they believe that such children should be cared for by whatever agency is best equipped to deal with the particular child. To all these arguments the defenders of the parental school reply that when commitment to an institution is necessary, a step that is taken only after all less drastic procedures have failed, it is better to have the institutionalization under the school's control, and thus be free from any taint of reformatory or penal institution. They point, also, to the fact that a parental school can be operated as an educational and not a penal institution and that it may have both the personnel and the facilities for studying the problems and for effecting the readjustment of the children committed to its care. In general, however, the parental school is not looked upon with favor and seems to be losing rather than gaining in professional esteem. R.V.M.

PARENTS ASSOCIATIONS—See HOME AND SCHOOL COOPERATION.

PARENTS, RIGHTS OF. In the early stages of development of the English common law, from which our American law derives, the general rule was, for all practical purposes, that a father had power of life and death over his children, a rule which prevailed in early Roman law. With the passage of time, this absolute right of the parent to control the child as he would a piece of property has been diminished, if not abolished, and the child has been given certain rights in his own name. In addition, the State as

such has assumed parental responsibility at many points.

It is fundamental law that the State, as *parens patriae* to all children, may deprive the parents of the custody and control of their children if it should be determined that the parents are unfit and unsuitable to have such custody and control. Juvenile courts have been established with the right to interfere with parental control and to change the parental guardianship over children if such parents neglect, abuse, abandon, fail to support, or fail to prevent the delinquency of their children. Child labor laws (*q.v.*) are another form of statutory control exercised by the State in derogation of parental rights to dictate the activities of their children. Compulsory school laws, now existing in all forty-eight states, have been declared constitutional, although they deprive parents of definite rights to control the conduct of their children. Other laws regulating children afflicted with communicable diseases, requiring the licensing of amusement centers, and affording general protection to children likewise assume certain parental authority. Within the school itself, the constitutionality of compulsory vaccination laws has generally been upheld. The parent has no right to demand that his child attend any particular school, the school board being vested with broad discretion to assign students to such schools as in its judgment may be best. This doctrine applies to the practice in some states of requiring a separation of races; this practice has been sustained against constitutional attack, provided only that equality of facilities and opportunity is made available to all.

However, notwithstanding state impingements upon parental authority, the parents as natural guardians of their children have basic control over their activities. As the Supreme Court of the United States once said:

"The child is not the mere creature of the State; those who nurture him and direct his destiny have the right, coupled with the high duty, to recognize and prepare him for additional obligations." (*Pierce v. Society of the Sisters of the Holy Names*, 268 U. S. 510 (1925)).

In terms of the school scene, this right has its most important application in issues where the parent attempts to control the courses or subjects his child shall study in school. Although the issue has not received much judicial attention, it appears that the

State has the right to prescribe specified courses of study. In the absence of such statutory prescriptions, there is a contrariety of judicial views where a parent objects to his child being required to study any given school subject. It is probably the weight of authority that the parent may make a reasonable selection of studies for the child to pursue, provided always of course that school discipline is not adversely affected. Thus courts have declared improper the actions of school authorities in expelling students for refusing to study grammar or social dancing where parents object to such studies. On the other hand, some state courts have upheld schools in expelling students for refusal to study music, declamation, rhetoric, or composition. Needless to say, even where a state does allow reasonable parental choice as to subject matter, nowhere does the parent have the right to dictate the mode of instruction.

The Supreme Court of the United States has had occasion to address itself to the problem of parental rights in the school. In the famous *Pierce Case*, cited above, the Court declared unconstitutional as unduly infringing upon parental rights an Oregon statute forbidding attendance in parochial schools by requiring all pupils to attend public schools. The parent, said the Court, could be required to send his child to school, but could not be required to send him to a public school; the choice was his. Two other cases before the Supreme Court involved attempts by states to forbid, rather than require, certain courses; in both, the Court declared the laws unconstitutional as improper infringements upon parental rights in the education of children. In *Meyers v. Nebraska*, 262 U.S. 390 (1923), Nebraska attempted to restrict and forbid the teaching of the German language during the First World War, and the Court forbade the enforcement of the act as an unconstitutional restriction of the rights of parents and teachers. In *Farrington v. Tokushige*, 273 U.S. 284 (1927), the Court invalidated a Hawaiian statute which attempted to impose extensive regulatory provisions on foreign-language schools, principally Japanese schools. In declaring the act unconstitutional, the Court said that although it was aware of the grave problems which motivated the statute

"Enforcement of the Act . . . would deprive parents of fair opportunity to procure for their children instruction which they think important and we cannot say is harmful. The Japanese parent has the right to direct the education of his own child without unreasonable restrictions; the Constitution protects him as well as those who speak another tongue."

PARKER, FRANCIS WAYLAND (1837-1902). Colonel Parker has earned a secure place in the history of education, especially of elementary education, in the United States. One of his most significant works furnished a nexus by which Americans came better to know Pestalozzi, Herbart, and Froebel (*qq.v.*); another established him as one of the chief interpreters of improved educational theory and practice of the period between about 1875 and the opening of the twentieth century. The posts by means of which he was able to accomplish this large measure of achievement were his superintendency of the schools of Quincy, Massachusetts (1875-1880), and his principalship of the Cook County, Illinois, Normal School (1883-1889). These administrative posts gave Parker's theory a chance to test itself in the hot crucible of actual school practice.

As Interpreter of European Educational Theory. Parker was an important link in the catenation of leaders by which Pestalozzi's salutary influence on elementary school geography was developed and made effective. This influence—through Ritter in Germany, Guyot, the Swiss, at Princeton University. Parker and his students (notably Frye)—was a definitive and permanent contribution to the elementary school curriculum. By it, geography was transformed from an encyclopedic subject to a "study of the earth as the home of man". It had been an exercise in mechanical memory of terms and of unassociated factual fragments. Through this movement, of which Parker was an important part, it became a thought-provoking study of the cause-and-effect relations between physiographic conditions on the one hand and human activities and social life on the other. Ritter and Guyot developed the new science; Parker and his disciples adapted it to elemen-

tary school purposes, stressing home geography as the point of departure for the young child.

Of the doctrines of Herbart (*q.v.*) and his European followers, it was the doctrine of concentration which appeared to be basic to Parker. Herbart's immediate followers in Germany, especially Ziller and Rein, had tried to develop curricula in which all activities were related to history and literature as the core of concentration. Parker placed geography at the core. To him, concentration was not just a structural curriculum device; it was a basic principle for unifying the experiences of a growing child. "The doctrine of concentration," he wrote, "is itself a science of education that will absorb the attention of thoughtful teachers for centuries." The perennial out-cropping of this concept suggests real prescience in Parker's judgment. Whether labeled as the project curriculum, or as unit teaching, or as integration, or otherwise, there is something basic in this concentration concept—if survival value is a measure of basic quality.

Of the Froebelian doctrines, those of unity, motor expression, and social participation were tirelessly preached and applied by Parker. He acknowledged Froebel's (*q.v.*) concept of unity as a source of inspiration in his educational thinking, and cited it as partial support for a concentrated curriculum. Froebel's stress on motor expression as an aid to growth was focal in Parker's training of teachers at the Cook County Normal School. Motor expression was justified chiefly on the grounds that expression helps thought and thought is necessary for expression. The effort to draw a map impels to more accurate thinking on what a map represents. It was a distinctive contribution of Parker that he saw the implications of these Froebelian theories for the growth of children of elementary school age; he urged that they be projected upward from the kindergarten, where they had first been instituted.

Improved Methods. Parker, by means of the journal issued by him and his Cook County Normal School colleagues and by means of the enthusiastic teachers who spread his vitalizing influence, has had an enduring effect on elementary school methodology. Examples of this phase of his work survive especially in the fields of geography and

reading. He attacked the early and exclusive devotion to oral reading and pleaded for silent reading, which he conceived to be psychologically a very different process. One was a form of expression, the other a form of thought-getting. Present-day reading methods have had persistently to reiterate this truth. (See **READING, METHODS OF TEACHING**).

Parker had to meet some of the opposition, both at Quincy and in Illinois, familiar to contemporary advocates of the "new education". His new geography was ridiculed as setting up "mud-pie factories"; he was accused of "neglecting the 3 R's." In spite of this, he persevered, and any complete history of progressive education (*q.v.*) must accord his work an honored place. **P.R.V.C. References.**

PERCENTILE. Percentiles are points on the base line of a frequency distribution which divide the number of cases into one hundred equal parts. Since neither scores nor ranks have any absolute significance, a

PERCENTILE CURVE — PERCEPTION

given score may be high or low depending upon the difficulty of the test, the number of questions included, and the scoring weights assigned; while a given rank may be high or low, depending upon the size of the group. The conversion of scores and ranks into relative units, such as percentiles, makes their interpretation more meaningful.

Percentiles are not frequencies nor are they per cents of test questions answered accurately. They are per cents of a group falling below designated scores or values. A *percentile rank* means the rank of a given score among 100, as though 100 individuals had been tested and ranked. For example, if 75 per cent of a group have test scores not greater than 62, then a score of 62 corresponds to the 75th percentile, and a pupil who has earned a score of 62 has a *percentile rank* or *percentile score* of 75.

As a frequency distribution may be divided into a hundred parts, so may it be divided into any other convenient number of parts. The most commonly used divisors yield *deciles*, *quartiles*, and *quintiles*.

Deciles are the percentiles which divide the number of cases into ten equal parts. The first decile is that point below which fall ten per cent of the scores. Each successive decile includes an additional ten per cent. For example, the sixth decile is that point below which fall sixty per cent of the measures.

Quartiles are the percentiles which divide the number of cases into four equal parts. The lower quartile (25th percentile) is the percentile below which lie twenty-five per cent of the measures and above which lie the remaining seventy-five per cent; the second quartile (50th percentile) is the median; the third quartile (75th percentile) is the percentile below which lie seventy-five per cent of the measures and above which lie the other twenty-five per cent.

Quintiles are the percentiles which divide the number of cases into five equal parts. The first quintile is that point below which fall twenty per cent of the measures. Each successive quintile includes an additional twenty per cent. For example, the third quintile is that point below which fall sixty per cent of the measures.

Where scores are available for a large and presumably representative sampling of a specified population, *percentile norms*, which in-

dicate the percentiles to which given scores correspond, furnish a useful basis for comparing and evaluating the status of similar individuals and groups. From the *percentile scale*, which furnishes the percentile equivalent for each score, it is a relatively simple matter to find the percentile rank of any given score. The percentile scale may be graphically represented in the form of an ogive. The *percentile curve*, or *percentile graph* is an ogive on which the frequencies are expressed as per cents of the total number of cases. The ogive is an S-shaped cumulative frequency curve which readily yields information as to the number of cases or per cent of a group lying below any designated value. It shows the sums of the frequencies of all measures (expressed as a per cent of the entire group) lying below designated amounts of the trait and serves as a graphic method of finding the median, quartile deviation, and percentile ranks of test scores.

Percentile units are not of equal length throughout the scale, nor are they as reliable for extremes as for average scores. However, by allowing for the conversion of scores on different tests or in different traits into common units, they furnish a convenient method of equating scores. (See GRAPHIC METHODS: NORMS.) H.G.

PERCEPTION. The process of *perception* has been analyzed differently by various philosophers and psychologists, depending mainly upon the metaphysical and epistemological assumptions they hold. Without attempting to define perception according to any one of these schools of thought, we can term it an awareness, by means of sensory experience, of objects, qualities, and relations. Perception, particularly after the first few years of life, is not a mere recording of sensations. A child who is startled by a sound or flash of light cannot be said to perceive

PERCEPTION

in the same sense as he does later when he learns through experience to recognize the startling sound as a fire-gong, or the flash as lightning. It is extremely difficult to separate perception from inference making. We perceive things in terms of what they suggest rather than in terms of face appearance. It is for this reason that witnesses find it so difficult to describe "exactly what they saw" and that children are told they "imagined" things when they are sure they saw them. The fact that perceptions and inferences are interrelated and that what is actually perceived, as well as how it is perceived, is partly a function of one's interests, attitudes, and emotions has led to such personality-testing devices as Murray's *Thematic Apperception Test*, which presents pictures to the subject for his description—pictures depicting scenes that can be interpreted in various ways.

Perceptions are also affected by the context in which the perceived items appear. Lines of similar size but with different types of lines added to them at the ends appear to be of different sizes, a light flashed on in quick succession appears to be a moving light, the moon seems to move quickly through the clouds when in reality it is the clouds that are speeding in front of the moon, etc. The child's conception of the world, so well described by Piaget (*q.v.*), is full of errors derived from perceptual difficulties.

Throughout his philosophy, Dewey stresses the need for the validation of perception if knowledge is to result. Kohler and Koffka hold that we behave according to our percepts and not according to the world as it actually is. In distinguishing between the behavioral and geographic environments, they emphasize that the former comes to correspond with the latter (that is, our percepts come to correspond with reality) as we act and experience the effects produced, effects that are dependent upon the geographic environment. This is largely in agreement with Dewey who has built his whole theory of education on its relationship to experience. Dewey, however, is careful to point out that experience by itself will not necessarily correct false perceptions. Reflective thinking involving principles of logic must be applied.

It is seen that observational techniques so commonly used in child study may suffer from the wrong interpretation which is inte-

grated with the observation. Thus, agreement among trained observers watching the same child at the same time is frequently low. The attempt has been made to get observers to record in categories which would more nearly approach the "exactly what was seen" criterion. There is more agreement in such recording, but the data prove to be barren for any practical use.

Whether we perceive small units which we then add up or integrate into wholes, or whether we first perceive wholes the details of which we only later differentiate has been the subject of much controversy since the Gestalt psychologists elaborated the latter view. Actually, the problem is not completely an "either-or" one. The wholes of the universe are not always presented to us in the way that the whole chair may be in our view. Moreover, things are parts in one relationship, and wholes when considered from another point of view. Is it the letter, or the syllable, or the word, or the sentence, or the paragraph, which forms the whole and should be taken as the unit for beginning the teaching of reading? Only experiments can determine the answer. Experiments have shown that words can be perceived and recognized before there is any knowledge of the separate letters, and that for a majority of young children greater success is gained when reading starts with words, phrases, or short sentences. On the other hand, young children have been found not to be able to perceive the "whole" or "theme" of a picture. They name the separate objects which they see, without perceiving the relationships between them. Experiments with the Rorschach tests have demonstrated that the mentally retarded also give more "detail" than "whole" responses. One can thus say that perception begins with an object of a size depending upon the nature of the object and the perceiver and the perceiver's purpose, and that, as perception continues, details of the object may be differentiated while at the same time the object is integrated with others to form a new whole or pattern.

PERSONALITY. The development of personality has come into prominence in recent years as an important objective in education, an objective which centers its interest on the child as an individual—on the whole child. This newer departure contrasts with earlier ones aimed at the development of specific habits, skills, and attitudes. With the lessening influence of the family and the growing complexity of civilization, there is a demand that formal education be interested in the child's total adjustment as well as the mastery of certain isolated elements of learning.

Personality as a term suffers from vagueness and from having a number of different meanings. Allport¹ presents 500 definitions of personality. Certainly education is only to a mild degree interested in the development of personality in the sense of social reputation or superficial charm—the meaning of personality which is associated with Hollywood. Allport's own definition of personality is "The dynamic organization within the individual of those psychological systems that determine his unique adjustment to his environment." This definition includes a number of distinct concepts. In the first place, personality is thought of as pertaining to the *organization* of traits rather than the disparate accumulation of separate traits. Personality refers to the *uniqueness* of an individual—that which distinguishes him from another and gives him his distinct character. Personality also refers to the *adjustments* which an individual makes to his environment. Of these adjustments, his social adjustments are by far the most important. Reference is sometimes made to *personality adjustments*, which refers to an individual's emotional stability and the integration of his purposes around socially valuable goals. Adjustment in this sense does not refer exclusively to passive adaptation, but also to the

active processes of manipulation and mastery of the environment to gain one's ends. Personality adjustment has two foci of meaning. First, it refers to an individual's happiness and well-being, his sense of security and a general feeling of worthiness and adequacy. Second, it refers to an individual's ability to make himself acceptable in the various social groups of which he is a member.

Personality and *character* are two terms which are commonly bracketed together in discussions of educational objectives, and are often contrasted with each other. Allport speaks of character as personality evaluated, while personality is character devaluated. Character refers to the goodness or value of personality. In a more limited sense, it refers to the extent to which an individual is socialized in his conduct and attitudes. One commonly speaks of an individual as having a good character who has the qualifications of a good citizen. Personality, on the other hand, refers to the characteristics of an individual without attempting to pass judgment upon them or to indicate to what degree the individual's traits are socially acceptable and desirable. Sometimes personality is used to refer to all aspects of an individual, which would include his physique, the appearance that he presents to others, his intelligence, and his stock of interests, attitudes, appreciations, and ideals. May³ has defined personality as a man's social stimulus value; i. e., "the responses made by others to the individual as a stimulus."

The degree to which personality is influenced by heredity and by life experiences has not been finally determined. There is evidence which would indicate that some aspects of personality are to some degree inherited. However, identical twins living apart do not show a closer correspondence on personality questionnaires than do non-identical twins, siblings, or unrelated children who have had the same experience in living in different families. There are some who see the personality determined by various somatic and morphological factors—as, for instance, through glandular influences or through the influences of body dimensions. By far the most promising hypothesis today is that personality to a large measure is determined by experience, particularly experience in the first days, weeks, and months of an infant's life.

Studies of child development and clinical studies in child guidance have demonstrated the mechanisms of learning in infancy which would help to account for the variations in personality of children and adults in later years. Of special importance are the experiences in the family, and, in particular, the attitudes and relations of parent and child. Evidence is piling up to indicate that a considerable number of the distinct characteristics of personality are determined by the nature of the relationships between a child and its parents. For instance, accepted children develop well socialized and stable personalities, whereas children rejected by their parents develop aggressive and non-cooperative tendencies, show unstable qualities, and have tendencies toward delinquency.⁵

Modern psychology, in contrast to popular misconceptions, is impressed with the stability of personality. The average man thinks of personality as something like a suit which can be changed daily. It is commonly believed that one can adopt attitudes to fit the occasion, and that an individual can shift readily from being aggressive to being submissive, and from being buoyant and optimistic to being pessimistic. Intensive studies of individuals point, however, to the persistence of personality traits over the whole of the life span. The methods by which an individual meets situations today will closely resemble the methods which he used yesterday, last week, a year ago, or even twenty years ago. The persistence of personality traits is unmistakable. In understanding an individual in order to help him, one can assume the existence of a natural history of personality growth and development. The personality that one brings to a present situation is the final product of innumerable early experiences to each of which he has reacted, and which have helped to form the course of his present adjustments.

Considerable attention has been given in recent years to methods of studying a personality. At first, there was considerable hope that psychometric methods which have been so successfully used in the measurement of intelligence, aptitude, and achievement, could be adapted to the study of personality. In general, however, the results of these attempts have been disappointing. This is due partly to the fact that in giving an individual a

paper and pencil questionnaire, one has to depend upon his willingness to cooperate and answer the questions truthfully. One has to depend also upon an individual's ability to view himself objectively, and to put aside the temptation to throw a favorable light on his feelings and attitudes. Today, experimentation is going on with less direct attempts to measure or describe personality. Projective methods, by which an individual is lead to reveal his underlying phantasies, wishes, and attitudes by responses to incomplete or undifferentiated stimuli, are being developed. Among these the Rorschach technique (*q.v.*)—a series of ten symmetrical ink blots—is being widely used and is yielding promising results. Perhaps more basic to these projective methods are the clinical methods of personality measurement through direct observation and the use of interview techniques. With younger children considerable use is made of the child's reaction in a play situation, which combines observation with the principles underlying the use of projective methods.

Education is interested in the possibility of modifying personality. Just as personality itself is believed in large measure to be a product of early experiences, so it is believed that personality can be extensively modified by the wise selection of new experiences. However, it should be recognized that personality is not easily modified, but, as was said earlier, has considerable stability growing out of the adjustments that have been made to a myriad of earlier life experiences. Education needs perspective with regard to the timetable of personality change. Modification of personality must be thought of in terms of months and years, rather than weeks and days. A child, even when placed in the most constructive environment, will change its personality only gradually. Educators should recognize that personality can be modified only to the degree that the child's experiences are modified. This usually means that if the personality is to be improved, there must be a somewhat radical change in the child's conditions of living, which usually means a change in home or school, a summer spent at camp, a change in curriculum or teacher. The most important factor in the modification of personality may be found in the personal and social relationships of the child. Personality is changed more through changing

parents, teachers, counselors, and playmates, than through changing clothing, sleeping arrangements, food, or books. Even though personality in its more important phases can be changed only slowly, and in moderate degree, the development of personality still remains as one of the most important aims of education. (See CHARACTER EDUCATION.)

PERSONNEL WORK, STUDENT — See GUIDANCE.

PERU, EDUCATION IN. Peru is a country double the size of pre-war Germany, but with a population of only about 7,000,000. About 10 per cent are of Spanish blood, 60 per cent are Indians and the remainder are *mestizo*. Due to the unfavorable climate of the high Andes these last two groups are physically underdeveloped. Except for the guano, all the riches in minerals, oils, agricultural products and also the transportation system and banking are predominantly in foreign hands. Most of the inhabitants are employed in agriculture, but two thirds of the cultivated land belongs to the church and the *Latifundistas* (wealthy landowners). The costly war of the Pacific against Chile and the continuous strife among conservative cliques hampered Peru's development during the 19th century. These inner struggles had not abated to the end of the Benavides government in 1939. But a liberal, American and pro-Indian movement, the *Aprismo* under the leadership of Haya de la Torre, arose since 1923 against the ruling conservatism. It united the majority of the population and

seemed to sweep Haya into the Presidency in 1931, when he was arrested and his party suppressed. The government of Manuel Prado (1942) cautiously veered in the direction of democratization.

Under these circumstances the cultural level of the country as a whole is rather low. Nine-tenths of the Indians are illiterate. Many still speak only their native language, *Quechua*. Their old culture which culminated in an elaborate school system for boys and girls of the Inca aristocracy was wiped out by the conquest. It introduced the scholastic medieval system which centered around the oldest American University of San Marcos in Lima (1551), in which the new free spirit of the Renaissance was not admitted. The Republic, under the Liberator San Martin, seemed to open a new era under the influence of French revolutionary ideas. In 1922 he invited to Peru the Scotchman, Don Diego Thompson, who had introduced the Lancastrian system in Argentina and Chile. He did the same in Peru and founded a normal school. In spite of many school laws and reform projects in the 19th century and of the work of the American Bard Commission of 1920, the political situation has prevented a basic change. But there is hope that the awakening of the national spirit and the understanding attitude of the government will definitely improve the educational situation. The Education Act of 1941 is promising. The problem of how to relieve the Indian from his bondage by an education based on his particular needs is clearly stated and better financial provisions for that education have been made. But it is also clear that the progress of education will finally depend on the progress of agrarian reform and industrialization. The state of education in 1942 was about the following: The administration is centralized in the Ministry of Education and its departments. But political and enormous geographical difficulties restrict its efficiency. Nearly 10 per cent of the population—against 17 per cent in U. S. A.—attend elementary schools, which are compulsory by law (where they exist) for all the children from 7 to 14 for a course of 6 years. But nothing is certain about the number of days the schools are open, or the average attendance of the pupils. Three per cent of the elementary school population continue in the forty-eight secondary schools and normal schools.

Most of them are directly or indirectly church controlled. The secondary schools have two cycles of three years each. The first is general, the second has some rigid courses of either a utilitarian or an academic character (science or letters). The academic courses prepare for the University Entrance examination. Elementary teachers attend a secondary school for four years and go to the normal school for another three years. But in 1942 no more than 20 per cent of the teachers in service held certificates of a normal school. Secondary teachers complete the secondary school and need four more years of scientific and educational training in two special institutes or in the university. But few of the secondary teachers have graduated from these institutions. Among the 5 universities—one is private, the Catholic Univ. of Lima—and the different higher technical institutions, the university of San Marco in Lima holds a special rank. It has both medieval (philosophy, theology, etc.) and modern faculties (science, economics and politics). Its development too has suffered from the political unrest of the country. It was closed by the government from 1932-1935, when the movement for democratization of the Latin American Universities which had started at the University of Cordoba in Argentina in the twenties spread to San Marco. It has attained a certain degree of autonomy with respect to curricula and financial administration. That is a hopeful sign that a new era is finally coming. F.K.

PESTALOZZI, JOHANN HEINRICH (1746-1827.) Pestalozzi was born in Zurich, Switzerland, and received a careful rearing in a good home environment. His mother, although left a widow when he was only five years old, was able to send him through the Latin school and to the University of Zurich. As a youth he became greatly interested in the conditions of the poor Swiss peasants. Influenced by his grandfather, a pastor in a near-by town, he studied for the ministry,

but soon considered himself a failure in that career. He then studied law to prepare himself as a champion of the down-trodden masses. His revolutionary ideas brought him into conflict with the government, and his usefulness as a lawyer was at an end.

In 1769, he bought a farm, which he called "Neuhof." Here he launched an experiment to improve the conditions of the Swiss farmers through education. He had read *Emile* and had tried to bring up his young son according to Rousseau's principles of naturalism. The experience convinced him that these principles needed some modifications in practice; he therefore took into his home a group of ragged, vagrant children and attempted to give them instruction in the rudiments and in religion and morals, while they supported themselves by industrial work under the influence of a good home environment. The experiment was an educational success but a financial failure and had to be abandoned when the reformer became bankrupt.

In 1781, Pestalozzi wrote his great didactic novel, *Leonard and Gertrude*, a book that ranks among the educational classics. Much later he published a sequel, *How Gertrude Teaches Her Children*. In these books he expounded his educational ideals and described the methods by which they were to be realized.

In 1798, Pestalozzi was given the opportunity to turn from the pleasant task of theorizing about education to the more thrilling and difficult task of practising it. The government asked him to establish a school in an old convent at Stanz and entrusted him with the task of educating about eighty children orphaned by a war massacre. Here he began his experiments in educational method which were later continued at Burgdorf, where he first acted as assistant to the head teacher in the village school and later established himself in a school of his own. With several loyal and efficient assistants he continued his experimentation, and was able with the aid of voluntary contributions and government subsidies to open an institute for the training of teachers in his new methods. In 1805, the institute was moved to Yverdon, where for twenty years he continued his experimentation and the teacher-training work begun at Burgdorf. As the fame of the institute at Yverdon spread, students and

visitors were attracted from other countries, and the Pestalozzian philosophy and methods were carried to other nations, particularly Germany, France, England, and the United States.

Pestalozzi's object teaching was the beginning of an important and influential movement in modern education. The chief characteristic of the movement is the belief that education is a control of the development of the child from within instead of an imposition of adult standards from without. It is primarily concerned with the psychological control of the development of the child.

Pestalozzian Aims. Pestalozzi's ultimate goal was the social regeneration of humanity. He said that his sole aim was to stop the sources of the misery in which he saw the people around him. "I lived like a beggar," he writes, "in order to learn how to make beggars live like men." He desired to ameliorate the desperate conditions under which humanity existed, but instead of depending upon new forms of religion, new types of government, or new systems of economic organization, he turned to education for his solution of this age-old problem. He believed that the only way to change society for the better was through changing the individuals that make up society.

Pestalozzi believed that the genuine reform of society must begin with the elevation of the individual, and that the individual can be elevated only by putting into his grasp the power of helping himself. The only sure means of attaining the end sought is through the process of development. Although his aim is to secure a happier and more virtuous life for every individual, the process by which he hoped to bring about this desired end was "the natural, progressive, and harmonious development of all the powers and faculties of the human being." These powers lie dormant and latent in every child, merely awaiting an opportunity to unfold; education must furnish the opportunities for their unfolding. Pestalozzi likes to compare the education of the child with the development and growth of a plant. He writes, "Man, formed from the dust of the earth, grows and ripens like a plant rooted in the soil." Pestalozzi's main purpose was to discover the natural laws underlying the development of the head, heart, and hand of the child. Education is to provide the conditions under which this

development can take place naturally and harmoniously.

These ideas of Pestalozzi mark a striking change in aim. In the schools of his day, teaching meant the giving of information. To Pestalozzi it meant the development of the child in accordance with his inborn faculties.

Pestalozzian Curriculum. In general terms, Pestalozzi believed that the essential elements of an elementary education were language, number, and form; all the materials of instruction could be brought under this three-fold classification. In practice, however, the Pestalozzians retained the traditional names of the various subjects in the elementary curriculum. Some of the subjects were changed for the better and some were not, but all came under their influence to a greater or lesser extent.

As a result of the Pestalozzian emphasis upon oral object teaching, certain subjects (arithmetic, geography, elementary science, and language) were emphasized much more than others, and were greatly improved in character. As a result of the extreme application of his principle of proceeding from the simple to the complex, other subjects (drawing, music, reading, and writing) did not fare so well.

In connection with the teaching of "object lessons," Pestalozzi and his followers naturally made use of many materials used later in the teaching of the natural sciences. However, they usually designated such instruction by the term "object teaching," the phrase "elementary science" coming into use later, and the phrase "nature-study" still more recently. The object teaching was at first of a rather informal nature, the teacher making use of the common objects in the children's environment in order to enlarge the scope of their impressions and provide the basis for language expression. Later, however, this objective teaching became more scientific and highly systematized. Collections of physical, chemical, mineralogical, botanical, and zoological specimens were made available for observation by the children, who were required to learn to describe them in scientific terms. Still later, especially among the English and American Pestalozzians, these lessons in elementary science were looked upon as essential preparation for the advanced study of natural science and history in the secondary schools.

No subject in the curriculum was more completely changed by the Pestalozzian influence than geography. Before the time of Pestalozzi, geographies were mere compendia of facts, arranged in a logical encyclopedic manner. Even after the development of Pestalozzianism, this dictionary-encyclopedic type of geography continued to be taught in most localities, and it is not uncommon to find traces of it in our geographies to this day. This fact-geography involved the memorizing of all kinds of astronomical, physical, natural, and political data, usually presented in a catechetical, or question-and-answer, form. The pupils learned definitions, statistics, boundaries, capitals, products, exports and imports, populations, etc., and the teacher listened to the pupils recite these memorized facts. The application of oral object teaching to geography changed all this. A new study of home geography was introduced, based on the principle of proceeding from the simple and known to the complex and unknown.

The third subject that was greatly improved as the result of Pestalozzian theory was arithmetic. Before Pestalozzi, arithmetic involved "figuring" on paper, and was commonly known as "ciphering." Rules were memorized and "examples" worked according to these fixed rules. Pestalozzi replaced such processes with rapid mental calculations in connection with the counting and measuring of objects. He tried to develop real number ideas instead of meaningless words about numbers. These number ideas were gained by counting, measuring, grouping, and arranging concrete objects, lines, etc. This type of arithmetic was popular down to the end of the nineteenth century.

Pestalozzi made oral language one of the outstanding features of his curriculum. He was the first to introduce the oral language lessons which have become such a prominent phase of our modern elementary course of study. The children were encouraged to tell what they had experienced after they had been filled with sense impressions through their observation of objects. Thus language came to be a free oral description based on sensory experience rather than a reproduction of words read in a printed text, and correct-speech usage came to be stressed instead of the formal rules of grammar.

Writing, drawing, and music should have

been developed by Pestalozzi along with oral language as agencies for free expression. He did include these subjects in his course of study, but unfortunately they were influenced unfavorably by his principle of procedure from the simple to the complex. Because of his attempts to reduce each of these subjects to its elements and to present it logically, they were taught in a mechanical, lifeless, and ineffective manner. Children were started on learning to write by means of drills on lines, curves, and muscular movements. In drawing, years were spent on angles, geometric figures, and forms. In music, children were drilled on notes, scales, and tones. Long before the children came to the real writing of ideas, the real painting of pictures, the real singing of songs, they were thoroughly tired of these subjects. It is only in recent years that our modern educational psychologists have taught us that what is simple to the adult is not necessarily simple to the child, and that what is logical to the finished scholar is not necessarily logical to the child and therefore not psychological in its arrangement.

Pestalozzi, in so far as he taught reading, was satisfied to continue teaching it in the traditional manner, beginning with drills on the alphabet, and then proceeding through drills on syllables and words to phrases and sentences. Today we realize, as a result of the work of later educational psychologists, that the phrase or sentence is the simplest element to the child, and we begin the teaching of reading with these elements. Even arithmetic came under the influence of this mistaken principle at the hands of later Pestalozzians.

Pestalozzian Methods. Pestalozzi based all his method upon the principle of pupil activity. There were two steps in his procedure, impression and expression, and both of these must be carried on by the child himself. Pestalozzi said, "Sense impression of nature is the only foundation of human instruction, because it is the only true foundation of human knowledge." He believed firmly that observation must be the basis of all instruction. For this reason his instruction of children, especially in the early stages, consisted largely of having them observe, count, analyze, and name objects. He made use of the object-lesson, where learning comes through sense experience rather than through words. He insisted on oral teaching of all

subjects. The child was not to learn from a book; the teacher was not to hear the child recite from a book. The child's expression activities must come from the impressions gained from the observation of actual objects. Language expression, both oral and written, must grow out of the observation of objects presented to the various senses of the child. So it was with drawing. Geographical expression consisted of such activities as the modeling of land forms perceived on field trips. Arithmetical expression consisted of counting the windows in the room, of measuring the distance across the room, and of similar exercises in counting and measuring. Moral expression grew out of the incidents which arose in the daily lives of the children.

Pestalozzi abandoned the older deductive methods, whereby teaching began with rules and abstractions, for the inductive methods, whereby children began with simple elements of experience which they combined into larger meaningful wholes. He recognized the principle that learning must proceed from the known to the unknown, which to him meant from the simple to the complex. He bitterly criticized the then prevalent method of "teaching the unknown by means of the incomprehensible." He reduced all subjects to their simplest unanalyzable elements (their *A B C's*), and then taught these subjects by carefully graded steps. Nothing was to be learned which was not readily understood and easily mastered. The application of this principle to the teaching of reading, drawing, and music has not been very effective, but its effect upon the teaching of arithmetic, language, geography, and elementary science has been most praiseworthy.

The principle that formed the core of the Pestalozzian method was that of proceeding from the concrete to the abstract, from the particular to the general. He protested vehemently against teaching generalized ideas to the child in the form of meaningless words, and insisted that the child must express his own ideas as the result of the impressions gained from concrete observation and experiences. Pestalozzi's great contributions to the new educational methods were: (1) the study of real objects, (2) learning through the various senses, (3) individual expression of ideas. One of his limitations was that his efforts were spent largely in the perfecting of the elementary steps of instruction. The

second was that he knew nothing about the psychological control of mental organization, of what went on in between impression and expression. It was along these lines that his disciple, Herbart (*q.v.*), was to make his great contributions.

Pestalozzi was opposed to the harsh, brutal discipline which for ages had characterized the schools, and tried to substitute for it a discipline of sympathy and love. He wanted to reproduce as far as possible the atmosphere of a good Christian home, gentle and refined. When a father visited his school and said, "Why, this is not a school, but a family," Pestalozzi was very much pleased. His discipline of "thinking love" was a natural outgrowth of his conception of education as the development of the child rather than the pressing of the child into molds of adult behavior. E.H.W.

PHENOMENALISM. Phenomenalism is the point of view that people know things in the outer world not as they really are but as they are experienced or appear to be. The phenomenalist believes that there are two worlds: the world of things as they actually exist and the world as it is conceived in the mind of the observer. Only this latter world of mental creation can be known. For instance, a red color is not considered to be an inherent quality of an object but what it is perceived to be. W.A.S.

PHILANTHROPY, EDUCATIONAL. Educational philanthropy refers to the private giving of money for the direct support of public or private schools or for building up endowments for such institutions. Non-public schools derive a relatively large proportion of their incomes from gifts and subscriptions and from the income derived from endowments built up by private subscriptions. Private gifts and grants comprise a relatively

small proportion of the income of public educational institutions.

Private support of education dates from early colonial times when schools of all grades were controlled by the church and supported almost entirely by private subscriptions. The growth of publicly controlled schools and the greatly increased public support in recent years has greatly reduced private support of education in all but the private schools. Today private schools enroll approximately 10 per cent of the children in the elementary grades, 7 per cent of the pupils in high school, and nearly 50 per cent of the students of collegiate grade.

An analysis of the income of institutions of higher education shows that both public and private schools are the recipients of endowments, gifts and grants. In most cases the public endowments are derived from public funds, whereas those of private schools have been built up by private subscription. Gifts and grants from private sources accrue to both public and private schools, although the proportion is much greater in the case of the private ones. In 1938 receipts from endowments contributed \$64,722,732 or 24.9 per cent of the income of private institutions of higher education. In the same year, receipts from private gifts and grants amounted to \$4,535,238 or 1.7 per cent of the income of publicly supported institutions, and to \$32,373,019 or 12.5 per cent of the income of privately supported institutions.²

Since the financial depression of 1929, there has been a definite tendency toward the decrease of income derived from endowment funds which has made it necessary for private institutions to seek new sources of revenue. One form this quest has taken has been the demand for governmental support of private schools. (See FOUNDATIONS, PHILANTHROPIC.)

PHOBIA. A phobia is an intense, morbid, irrational, and uncontrollable fear caused by

objects do not ordinarily constitute fear-exciting stimuli, such as dogs, cats, chickens, lightning, darkness, etc. Such fears, which attach to specific objects or situations, are usually the outcome of some specific process of emotional conditioning, usually in early life, whose cause may have been forgotten or repressed because of its painful character. Thus the unreasonable fear of flying creatures in a twenty-seven-year-old teacher was traced to the unexpected flying of a chicken against her face when she looked into a barrel. A feeling of "numbness and heart-stabbing fright" still induced in a twenty-eight-year-old man by lightning, wind, or rainstorms was traced to a terrific storm that occurred when he was seven, in which the sight of his mother's worried countenance added to his fright. In some instances factors other than conditioning are responsible, and a large number of phobias represent the attachment of fear to an object as a means of lessening the anxiety which has developed because of basic emotional insecurity or the frustration of instinctive drives.

There are nearly as many specific phobias as there are situations that can be experienced. However, the process of acquiring the phobia is the same, regardless of the particular phobia in which the process finally results. Some of the more common phobias are claustrophobia (fear of enclosed places), agoraphobia (fear of open spaces), acrophobia (fear of high places), pyrophobia (fear of fire), nyctophobia (fear of darkness), misophobia (fear of dirt or contamination), ailurophobia (fear of cats), and phobophobia (fear of fear).

The victim's recognition of the absurdity of the fear and his knowledge that it has no rational basis usually do not effect a cure unless the real cause is discovered and the emotional effects extinguished by the method of expression—that is, recall and verbalization of the causative incident and reliving of the emotional experience. Expert assistance is usually required to unearth the cause of a phobia that has transferred to a different kind of object or situation than that which originally gave birth to the fear. The result of this transferral is known as a *symbolic* fear or phobia.

It is clear that the teacher rarely has the training and the facilities for dealing with

PHONETIC METHODS (READING) — PHONETICS

such phobias as may be found among children. Child guidance clinics (*q.v.*) are equipped to give these children the necessary professional assistance. (See FEAR).

PHONETIC METHODS (READING)

—See READING, METHODS OF TEACHING.

PHONETICS. Phonetics is the science of speech sounds. The fields of phonetic study most generally found in the curricula of colleges and universities are: (1) experimental phonetics; (2) comparative phonetics; (3) historical phonetics; and (4) study of phonetic alphabets, which is also found occasionally in the secondary schools and even in a few primary schools.

Experimental phonetics is usually presented by means of laboratory equipment, such as oscillographs, kymographic drums, tuning forks, sound filters and spectra, and recording machines. Here the emphasis is put upon the measurement and description of the acoustical phenomena of speech sounds from an objective point of view. Speech sounds are analyzed according to their physical properties. Sometimes, the relationships existing between the anatomy of the speech mechanism and speech sounds are stressed.

Comparative phonetics, as the term implies, deals with a study of the speech sounds and intonations of two or more dialects or languages. Phonographic records are ordinarily employed in classroom demonstrations and practice periods. Thus, the like and unlike aspects of say, Southern American Speech and New England Speech, or French and Spanish may be studied.

Historical phonetics traces the mutation of speech sounds from one age to another. For example, courses in the history of the English

language often include a consideration of the sounds of English speech from the age of Beowulf down to the present time. Vowel and consonant changes are described and accounted for.

The study of phonetic alphabets in speech courses is widespread, especially in the eastern part of the United States. Since there are approximately forty speech sounds in American speech and only twenty-six letters in the English alphabet, additional symbols are needed when consistency of written representation of pronunciation is needed. Thus, the words *certain* and *curtain*, although spelled differently, are pronounced alike except for the initial sound in each word. The rendering of these two words into phonetic transcription provides for a consistent representation: **kə-tən**, **sə-tən**. Words phonetically represented are known as *ear words* and those spelled are called *eye words*. The following nursery-rhyme sentence is rendered half in eye words and half in ear words:

Hickory, dickory dock,

ðə maus ræn ap ðə klak

The phonetic characters used in the example are those of the International Phonetic Alphabet, commonly referred to as the IPA, the most widely used of all phonetic alphabets, and adopted by the International Phonetic Association. Its chief educational uses have been found to be: (1) as a tool in the study of pronunciation; (2) as a device for describing the speech patterns of the speech-handicapped; (3) as a procedure for building articulation tests; (4) as a means of constructing rehabilitation exercises and drills in articulation and enunciation; (5) as an aid in ear-training. (See SPEECH EDUCATION.)

PHONIC METHOD (READING)—See **READING, METHODS OF TEACHING.**

PHONICS. Methods of teaching word recognition by teaching the sound equivalents of printed letters and phonograms and the technique of blending them so as to form words are called phonic methods. Such methods, when mastered, provide the child with a means by which most unfamiliar words can be deciphered. They have fallen into disfavor as systematic methods of teaching beginners because they tend to retard rate of reading and to emphasize mechanics at the expense of comprehension. It is recognized that the ability to identify, pronounce, and blend common word elements is necessary for independence in word recognition. Many children acquire this ability with little or no specific teaching. The majority are helped by a planned program of phonic instruction supplementary to the basic sight recognition approach, and for the few pupils who do not make much progress with the usual sight methods, a systematic phonic method is frequently very helpful.

Phonic readiness is usually developed by giving practice in finding words that rhyme, words that begin with the same sound, etc. Letter sounds and phonograms are introduced by pointing out similarities and differences in words that have already been learned as wholes. In sounding words, there are several methods, each of which has its advocates. The word *land*, for instance, may be sounded *l-a-n-d*, *l-and*, *la-nd*, or *la-and*. Each of these procedures works well with some words and poorly with others. A good reader needs flexibility in his methods of attacking words and exclusive devotion to any single procedure is undesirable.

In teaching an adequate method of attack on long words, the main requirement is emphasis on a systematic procedure of dividing the word into recognizable groups of letters and combining them in left-to-right order to get the whole word. The teaching of grammatical rules of syllable division is not essential. If the pupil has difficulty learning these more or less arbitrary rules, he should be encouraged to look for letter groups that seem to him to form natural units. In many schools syllabication is taught in spelling rather than in reading lessons. (See **READING, METHODS OF TEACHING.**)

PIAGET, JEAN (1896-). For a number of years, Piaget has been, simultaneously, professor of child psychology at the University of Geneva, co-director with Pierre Bovet of the Institut J. J. Rousseau (a teacher training institution affiliated with the university) and director of the Bureau International d'Éducation in Geneva, Switzerland. The significance of his work for modern education stems from his active participation in all three fields of endeavor.

His earliest researches on the development of language and logical reasoning in young children bear the earmark of his still earlier training and original work in zoology. He collected and classified stenographically recorded conversations of four to six year olds—much as he used to collect, classify and analyze changes in function and structure in mollusks of the Valaisian Alps. Then, assisted by an ever increasing number of inspired student collaborators, he undertook a great number of developmental investigations on concept formation and changing methods of reasoning in children ranging from five to thirteen years of age. Utilizing spontaneous questions of children as well as their replies in informally conducted, though roughly standardized and verbatim recorded, interviews, he was thus able to outline a remarkable developmental picture of the child's progressively maturing explanation of various

phenomena. Such phenomena ranged from "being one of three brothers" to concepts of family and country, the origin of thoughts, names and dreams, concepts of life and consciousness, the origin of sun, moon, air and other processes of nature, including simple man-made machines as well as more complicated mechanisms.

Utilizing an unexpected and brief experience as a professor of sociology, he proceeded, upon resuming his career as a psychologist, to a penetrating experimental verification of Durkheim's moral sociology—through a developmental study of the child's sense of moral obligation and responsibility. On the one hand, he compared children's actual practice in playing marbles with their developing awareness and verbalized concept of the rules of this game. On the other hand, extending his earlier researches, he inquired into their methods of moral reasoning through clinical interviewing techniques. He was thus able to probe the manner in which children of different age-levels judge and compare simple moral situations involving children and adults as well as children playing and working among themselves—including such concepts as different forms of lying, degrees of severity and fairness in punishments, etc.

In summing up and interpreting his findings, Piaget attempts to account for the progressive changes and maturation of child language and thought in terms of his theory of decreasing egocentricity. While stressing the basically biologically given nature of intelligence, in keeping with his early zoological background, he actually arrives at a social psychological explanation here—emphasizing the causal rôle of interpersonal relations between children and adults as well as among children themselves. Under the influence of Bleuler, Janet, Blondel and, especially, Durkheim, he ascribes the most primitive and immature stages of child language and thought to a relative lack of socialization or of experience in balanced give-and-take forms of communication among human beings. On this analysis, the onesidedly oppressive influence of adults would at first reenforce the initial, "spontaneous" self-centeredness of children—as a result of helpless dependence on adult omniscience and omnipotence. Conversely, the more egalitarian nature of contacts among children them-

selves would facilitate and largely bring about the socialization of child mentality—through the increasing needs and opportunities for give-and-take cooperation, independence, reciprocity, and relatively coercion-free communication which can only obtain among social equals. It is thus a struggle between the constraining influence of authoritarian adult prestige and the liberating, properly socializing influence of democratic cooperation among children as equals. More or less slowly, the latter comes to prevail and the child becomes intellectually less dependent and hence less egocentric, more objective and realistic in all forms of reasoning. For instance, he becomes less animistic in his view of the physical world, i.e., he eventually ceases to endow inanimate objects with his own characteristics and conscious motives—as he progressively learns to differentiate between himself and the rest of the world. He comes to recognize and to reckon with the other person's point of view under the impact of his recurring contacts with other children who can freely contradict him and whom he in turn can freely contradict. From initial egocentric unawareness of himself and of his egocentrically distorted perspective of things and persons, he arrives at a more objective perspective. His socialization consists of his growing recognition that others do not necessarily think as he does and of his increasing ability to see himself as others see him.

A great number of European and American investigators attempted to verify Piaget's findings on developing child thought. The number of investigations thus inspired by his pioneer studies in itself attests to the value and significance of Piaget's work. In the light of such follow-up studies, his findings on the extent of egocentric speech as such would appear least unequivocal, while his discoveries on the child's conception of physical and, especially, moral phenomena would seem rather correct. Further studies are needed and these may well result in some clarification of existing discrepancies even in the matter of child languages—since Piaget's followers so far have failed to account for differential factors of language and general cultural environment of the children studied by them, in comparing findings with those in the original researches. His theory

of egocentricity, too, bears further scrutiny since it does not quite fit certain relevant clinical observations. Even though somewhat inconsistent and rationalistic in relation to more dynamic factors of social-emotional growth, it provides a suggestive partial framework for the whole field of child development and child education.

Piaget is a very inspiring teacher and practitioner of progressive methods of education. Future educators and practicing pedagogues have been coming to Geneva in great numbers during the last two decades in order to work with him not only at the university and at the Rousseau Institute but also at the International Bureau of Education. Carrying over his research theory of coercion vs. cooperation in relation to egocentricity in children, he came to emphasize principles of the activity school for all age-levels, closely following Dewey and Claparède (*qq.v.*). In addition to thus stressing issues of educational "self-government" by children, directly influencing numerous practicing and future teachers, he has also been influential in spreading such principles through ministries of education in many European and South American countries through pedagogical publications of the International Bureau of Education and through yearly conventions sponsored by the latter agency, under his leadership. (See CHILD PSYCHOLOGY.)

PLACEMENT EXAMINATION. A test designed to afford a basis for the admission and classification of students in a particular subject is sometimes called a *placement examination*. Placement examinations usually provide separate measures of aptitude and of training in such fields as English, foreign languages, mathematics, and the physical sciences. They may be used in combination with or in lieu of tests of general intelligence in the guidance of college students. The training tests are valuable in diagnosis as well as in prognosis. (See DIAGNOSIS, EDUCATIONAL; GUIDANCE; PREDICTION OF SUCCESS.) C.C.R.

PLANT, SCHOOL—See ARCHITECTURE, SCHOOL; BUILDINGS, SCHOOL; CUSTODIAL CARE.

PLATEAUS, LEARNING—See LEARNING, CURVE OF.

PLATOON SCHOOL — PLATOON PLAN. The term *platoon* comes from the unique plan or form of organization in the platoon school, which provides for the division of the total pupil population of a specific school into two groups or platoons of approximately the same number of children. Under this plan of organization, the schedule of classes is so arranged that the children in one platoon are in regular classrooms or "homerooms" receiving instruction in the fundamental subjects and skills while the pupils in the other platoon are participating in special activities in specially designed and equipped rooms. At a given signal at specified times during the day, the two platoons exchange places. The children in Platoon A, who have been studying the fundamental subjects or skills in the regular classrooms, leave to engage in those activities that are scheduled in the specially equipped rooms or playgrounds in which Platoon B has been working or playing; while the children in the latter group go to the regular classrooms for the same type of study in which Platoon

A had been participating during the preceding period.

This division of the total population of a school into two platoons—the scheduling of classes in alternating groups so that every classroom and all the specially equipped rooms as well as playground facilities are in use as nearly as possible every hour of the school day—achieves the secondary purpose of the platoon school in providing an organization through which the most effective use of the school plant may be made. This economy feature can be seen easily by comparing the platoon school with the usual type of school organization in which a seat and desk are provided each child to be used solely by him during the school day. In the platoon school, a desk is used by a child in one platoon during one-half of the school day and by another child in the other platoon during the other half of the day. Through this sharing of equipment and space according to a schedule that emphasizes full utilization of the school plant facilities at all times, the school organized on the platoon plan can accommodate two *duplicate schools* functioning at the same time with a combined enrollment of nearly twice as many children as would be possible in the typical school organization.

The economies resulting from the use of the platoon plan, both in per capital operating costs and in relieving overcrowded conditions, are so marked that most of the critics of the platoon school as well as many of its ardent enthusiasts overlook the contribution its diversified curriculum makes to the all-round development of children.

The platoon plan of organization is only a means to an end in achieving the more fundamental contribution of the platoon school. Its primary consideration is to provide for children a rich, diversified, and well-balanced curriculum, implemented by extensive facilities in the form of specially designed and equipped studios, shops, laboratories, libraries, gymnasiums, auditoriums, and playgrounds in addition to the typical elementary school classrooms. An amount of time equal to that devoted to the intellectual development of the child is given daily to activities contributing to the child's social, physical, and æsthetic development, instead of providing only a few minutes each week

for the perfunctory participation in these activities as is characteristic of the typical elementary school. However, the unique plan of organization of the platoon school has attracted so much more attention than its program of studies that the terms "platoon plan" and "platoon school" have become synonymous in the minds of most people.

The first platoon school was organized in 1900 in Bluffton, Indiana, by William Wirt, Superintendent of Schools. In 1908, Mr. Wirt left Bluffton to become Superintendent of Schools in Gary, Indiana, where he introduced a plan of education later known as the Gary Plan (*q.v.*) and which included the platoon plan of school organization.

Practically every school system that has adopted the platoon plan has developed certain unique features based on a philosophy of its own. This difference in details and in philosophy, whether great or small, has resulted in a large number of names by which the various schools are called. Some of the names used today in referring to a platoon type of school are: *Work-Study-Play School*, *Semi-Departmental School*, *Duplicate School*, *Gary Plan School*, *Companion Class School*, *Alternating Plan School*, *Recitation-Study-Play School*.
W.V.N.

PLAY. Play is defined not by the type of activity engaged in but by the distinctive attitude which the player takes toward the activity. In play, it is the activity itself rather than the results which count. Though the player may work to improve his skill in the game, it is he who sets up his standards, and failure to achieve them does not result in loss of status. The relaxation derived from play comes not from the factor of rest (children commonly play "hard") but from the absence of emotional tension related to the activity. The player enters the game voluntarily and he is free to leave. For a child, play means in particular that there are no adult forces which constrain him, adult forces which keep him at the activity or which make him pursue the activity in a certain manner. Whatever values he may get from his play, he does not enter upon it because of these values. He plays because he enjoys it; when he does not, he stops playing.

Activities which are commonly called play do not meet all of these criteria. It has become customary to distinguish between free

play and organized play. In so far as the organization of organized play consists of a set of rules imposed by someone on the players, to that degree does the game lose its spirit of play. If, however, the rules of the game, whether taught the players by an outsider or not, are rules which they are ready to follow because of the game and not because of the authority, then even a highly organized game can have all the value of play.

Though a child plays without thought of furthering his development, the value of play to his development is exceedingly great. His active play exercises his muscles and brings about needed motor coordinations. Through needed play he explores possibilities in himself and in his environment. His investigations gain him new sensory experiences and add to and develop his stock of meanings. Though he is free to imagine and to dramatize, his play with things teaches him to respect reality. He learns that though he may say "this is only in fun," real actions have real consequences.

Besides serving as a means towards his physical and intellectual development, play is the chief medium through which the socialization of the young child takes place. As he plays more and more with children near his own age, he experiences relatedness to others. He feels both his likenesses to them and his differences from them and he gains a sense of belonging. He finds that even where there are no adult rules and regulations to obey, he cannot have things all his own way. Play with a group shows him that complete freedom—anarchy—is an impossible state, that companionship necessitates mutual adjustments. He thus learns that cooperation is fundamental to satisfactory living. Of course, play does not teach all children all these lessons equally well. Nevertheless it is the medium through which much of children's social learning is brought about.

Social adjustment and the learning of social relationships go hand in hand. Play affords children an opportunity to improve in both these areas. Through imaginative dramatic play, even when engaged in alone, the child re-enacts his world until he has its relations down to his satisfaction. The young child finds it difficult to figure things out in words alone. He needs more concrete symbols. With his toys he recreates scenes from his own life which puzzled him or which did

not turn out to his liking. He may play the same situation many times either so that he can have his desires on a symbolic level when he is denied them on the real level (a form of play which corresponds to daydreaming), or till at last he comes to accept the situation in the form that he knows it is going to occur on the real plane.

For the child to be able to work out his aggressions and his impossible hopes on a symbolic level with toys which represent the people and the things closest to him is considered by psychologists and psychiatrists to be of great therapeutic value. At the same time, these projective play techniques which permit the child's repressed and tension-producing desires to assert themselves reveal to the psychologist some of the causes of the child's behavior. (See PROJECTIVE TECHNIQUES). Great care must be taken in making the interpretation of the child's play since the same dramatizations made by different children may mean different things. The interpretations have been found most helpful when used as clues to further investigation into various aspects of the child's life. When psychologists have given parents possible interpretations of their children's play, the parents have themselves often been able to identify some of the specific factors operating to bring about certain behaviors on the part of their children.

Since social development involves moral or ethical development, it should be expected that any medium which provides their social development also provides for the moral development of children. Popular language recognizes this value of play in the expression, "learning to play the game," which has been generalized to mean learning to keep to the code of honor. In his study of the moral judgment of the child, Piaget (*q.v.*) watched children at play in games which had fairly definite rules and in which two or more players were needed. He found that the youngest children, who broke the rules most often, felt that these rules could never be changed and that they had been set up by some absolute authority. On the other hand, the children of eleven to thirteen who were still playing these games stuck closely to the rules though they saw no reason why the players could not change them if they wanted to. However, the changes had to be agreed to by all the players and once the new code

was decided it had to be obeyed. Piaget does not imply that the attitude that the group is responsible for the making and the keeping of its code of law, an attitude developed in the playing of group games, will necessarily transfer to an attitude towards social law in general. Indeed, he points out that certain factors in the playing of marbles, which help to develop such an attitude towards the rules of that game, are absent in many life situations, thereby preventing transfer of the attitude from taking place. He believes that the lack of adult constraint with regard to the rules of marbles playing, particularly for the oldest players, allows the children to grow out of their naive belief that all rules are divinely instituted, and to look upon rules as part of cooperative playing. It is because the situation is an autonomous one for the older marbles players that the "morality of duty" can change to the "morality of goodness."

Whether or not this generalization of Piaget's is upheld, it is seen that the manner in which children's play is supervised and guided will affect the kind of values which they derive from it. If the child is to learn certain rules of social living through the give and take of group play, then adult interference must be kept at a minimum. If children are to learn how to settle their quarrels, then they must be given opportunity to settle them as they arise during play. If children are to lose their timidity in the use of playground apparatus or to be helped not to develop it at all, then apparatus suited to their level of skill must be provided so that the adult's supervision need be little more than watching from a respectful distance to see that serious accidents are prevented. Aside from this, the function of adults on children's playgrounds is to help insure optimum conditions which will allow spontaneous and self-directing activities on the part of all of the children and upon occasion to introduce new games as well as new equipment.

If games are to retain their value of play, then games taught to children must be carefully suited to their age level. Highly organized games are not suitable for the youngest children. Indeed, practically all of the play program of children below the age of five should be supervised rather than directed. If the teacher or play group director wishes to broaden the children's play, he may do so in two ways without direct teaching. First, he

may introduce new equipment which naturally leads to new play. Secondly, he may widen the children's experiences by taking them on excursions, telling them stories, showing them pictures. Since children's dramatic play reflects their experiences, these new experiences will enter into and shape their play. Indeed, some schools are using this technique as one of their main pedagogical methods in the primary grades. Such a technique, even when used largely to facilitate learning, may at the same time retain many of the values of real play, provided the activity is not regimented. (See Toys.) B.B.F. and M.S.Q.

PLAY PRODUCTION—See DRAMATICS.

PLAY SCHOOL. A play school is an organized group of children who come together after school, and in some instances on Saturdays in winter and all day in the summer, to engage in a variety of educational activities under adult guidance.

The outstanding feature of the play school is the emphasis placed on play as a basis of learning and growth. Based on the theory that a child's present and future physical, social, emotional, and mental well-being is affected by the play activities in which he engages, much of the program of the play school centers around those forms of play such as dramatics, music, constructional, art, and physical activities which offer the greatest possible contributions to the development of the individual. In addition, trips and excursions are provided in order to help children develop or refine concepts relative to their environment. Hot lunches, mid-morning and mid-afternoon milk and rest periods, and physical examinations followed by necessary corrective measures are provided to pro-

mote the physical development of the children.

The play school is more or less a revolt against the traditional idea that "education" is synonymous with "schooling" and that learning takes place only from September to June each year. Play schools have been built on the idea that education is a continuous process which goes on the year around, in or out of school, winter or summer.

Play schools are more likely to be found in the larger cities where there is apparently more need than in less populated and rural areas for providing all day care and constructive activity for young children during the summer months and the late afternoon and on Saturdays during the winter months.

While the length of session, the activities provided, the age and type of children served, and the organization and administration of the program vary, the emphasis on play as a means of learning is characteristic of all play schools.

The play schools in New York City, sponsored by the Play Schools Association, an organization of lay and professional people, are among the better known play schools. These schools are financed by funds derived from both public and private sources. They are located in settlement houses, in public and private schools, in community centers, and housing developments. Playgrounds are used extensively for physical activities, including swimming and showers in the summer. In addition to many volunteer workers, each school is generally staffed with a director, one teacher for every twenty or twenty-five children, a clerk, part-time specialists, a neighborhood worker, a person qualified as a parent education leader, and kitchen and custodial staffs.

POOR-LAW SCHOOLS. In some of the early American colonies, particularly the Middle Colonies, schools for pauper children

were established as charity schools, financed by endowments and gifts. When the colonies became states, provisions were made in their constitutions and by legislative enactments for the establishment and support of such schools.

The pauper-school concept was an inheritance from the English class system, and was foreign to the principles of equality inherent in a republic. The schools were attacked bitterly by those who opposed the branding of the poor as a separate class and the development of such class distinctions in our democracy. Many of the people for whom the poor-law schools were intended refused to declare themselves as paupers, and thus made themselves ineligible to enter their children in these schools. As a result of such objections as these, the poor-school laws were gradually revoked and the idea of charity schools for the poor ultimately rejected by the American people.

PORTLAND PLAN—See PROMOTION.

POST-DOCTORAL EDUCATION. The objectives of post-doctoral education are the advancement of research and further training of younger scientists or scholars through study, travel, or added experience in field or laboratory. Of late years there has been a marked increase in the number of fellowships or grants-in-aid awarded to encourage study and research beyond the doctorate. The grants administered independently of the universities are from the national foundations, institutes, councils, and scholarly societies, including the Carnegie Corporation of New York, the Rockefeller Foundation, the Guggenheim Memorial Foundation, the National Research Council, the Social Science Research Council, and the American Council of Learned Societies. (See COUNCILS OF LEARNED SOCIETIES; FOUNDATIONS, PHILANTHROPIC.)

Among the better known administrative plans for post-doctoral education are those of the Institute of Advanced Study at Princeton; the Institute of Human Relations at Yale University; and the Advanced School of Education at Teachers College, Columbia University. The chief interest of the Institute of Advanced Study is post-doctoral work of the pure-research type, in which the educative experience comes through informal contacts among scholars engaged in cooperative tasks.

The Institute of Human Relations emphasizes the acquisition of research skills in related fields, an inter-disciplinary type of training. The Advanced School of Education seeks to promote the professional growth of doctorates who are actively engaged in educational work.

C.V.G.

POWER TESTS — See **STANDARDIZED TESTS**.

PRACTICAL ARTS EDUCATION. Practical arts education refers to instruction given in one or more of a group of subjects all of which involve practical skills and related knowledge. Practical arts education differs from vocational education (*q.v.*) or training in several important respects. Among the chief purposes of practical arts education are (1) to give tryout or exploratory experiences involving a variety of representative tools, materials, and processes used in the world of work; and (2) to give an appreciative understanding of a variety of activities, of processes, and of design as used in the practical arts in man's effort to provide clothing, food, shelter, utensils, tools, and many forms of machines and equipment used in modern life.

Practical arts education is prevocational in nature. It provides orientation for youth before a vocation is selected. It seeks to produce, as Dr. Frederick J. Bonser said, "intelligent consumers as contrasted with efficient producers"; the training of efficient producers is the chief concern of vocational education. Practical arts education is more general than vocational education.

One phase of practical arts education is *industrial arts education*, a modernized, expanded, and enriched form of the kind of instruction formerly known as *manual training*. There are corresponding phases in other fields. For example, school gardening and 4-H Club activities, as carried on in rural communities, are forms of practical arts education. Similarly, general courses in business education, such as introductory courses in junior business practice, typewriting, and bookkeeping are forms of practical arts education. Courses in general home economics, as commonly given in junior high schools and in some senior high schools, are also forms of practical arts education as distinguished from vocational education. Practical arts

education is not aided through federal grants under such acts as the Smith-Hughes Act of 1917 and the George-Deen Act of 1936. (See **INDUSTRIAL ARTS EDUCATION**.) F.T.S.

PRACTICE—See **DRILL**.

PRACTICE EFFECT—See **RETESTING**.

PRACTICE PERIOD—See **LEARNING**.

PRACTICE TEACHING—See **STUDENT TEACHING**.

PRACTICE TEST. A *practice test* ordinarily consists of a series of diagnostic tests, each followed by a number of practice exercises. The diagnostic tests and accompanying exercises are so arranged that the pupil can ascertain his own weak points and then turn to the particular practice material designed to correct such errors. Relatively few practice tests have been standardized or published (e.g., *McCall-Crabbs Standard Test Lessons in Reading*, Bureau of Publications, Teachers College, Columbia University). (See **INSTRUCTIONAL TESTS**.) J.J.

PRACTICUM. The term *practicum* has as yet achieved no fully standardized meaning, but in general it refers to the attempts of some institutions of teacher education to relate more closely the study of educational theory and practice with actual student teaching experience in campus schools or off-campus schools.

In many institutions the "practicum in teaching" takes the full time of the student for a semester or part of a semester in the junior or senior years and represents appropriate credits of work. In such cases the practicum includes both student teaching in a school situation, and conferences or seminars

devoted to a discussion of the problems met by the student in student teaching. The conferences or seminars may be conducted at the school or at the college and may be conducted by the critic teachers of the schools, or by the staff members of the college, or by both jointly. In this way the student is aided in analyzing, interpreting, and applying desirable principles of teaching in his student teaching. The conferences or seminars commonly devote attention to such problems as: the development of specific teaching techniques; methods of preparing, organizing, and presenting materials; classroom management; keeping of records; use of diagnostic and achievement tests; remedial teaching; and patterns of child growth and development.

In other institutions the practicum is a term referring to the attempt to integrate the regular college courses with the student teaching experience or with special field study experiences whereby the student gains first-hand acquaintance with the schools and community in which the student teaching will be done. In this case the college courses and the field studies together constitute a practicum in the professional study of teaching, the purpose of which is to plan classroom instruction so that the field study is made more meaningful and so that the field study in turn vitalizes classroom instruction at the college.

In still other institutions the term practicum applies to a regular course at the college, conducted prior to or parallel with student teaching, and covering such topics as the aims of education, the desirable conditions for achieving such aims, methods of child accounting, demonstration lessons, conferences, case studies, and participation and observation, but not including actual student teaching. (See *TEACHER EDUCATION*.)

R.F.B.

PRAGMATISM. The term, pragmatism, has been notable in education as the theoretical underpinning for the progressive education (*q.v.*) movement. If this movement has not one, but a cluster of meanings, it is due in part to the fact that pragmatism itself is not a single philosophy. On the contrary, there are a variety of pragmatisms, several of which have been particularly prominent in education.

When the term pragmatism was first lifted into philosophic prominence by Charles Peirce, the mathematician, it was used to denote a logical process intended to aid in making ideas clear. This process proposed that the meaning of an idea should be determined by the practical or pragmatic difference it would make if it were assumed to be true. As between two ideas, if there were no difference in effect, it could be concluded that either the difference was purely verbal or the two ideas meant the same thing.

This point of view remained almost unnoticed till William James (*q.v.*) gave it wide circulation. Before long, however, James made a significant extension of the notion. While Peirce merely put pragmatism forward as a logical way of clarifying ideas *if the ideas were true*, James proposed the pragmatic test for the nature of truth itself. Ideas were to be held true *if they worked*. In other words, if the practical consequences of acting on an idea brought an individual personal satisfaction, if they had a "cash value" (but not necessarily a monetary value, to correct a false impression this famous metaphor of James' has often created), the idea was to be considered true "in so far forth." While James contemplated limiting the application of pragmatism only to problems not otherwise verifiable, many of his followers applied it indiscriminately to problems where other criteria of truth would suffice.

In a brand of pragmatism, which he called humanism, the English philosopher, Schiller, extended pragmatism as an epistemology into a theory of metaphysics as well. If truth is affected by individual interest, choice, or purpose, then the truth must change both as interests change and as experience with consequences in action dictates. This in turn would seem to indicate that truth is not something antecedent to action but the outcome of it. Truth is made; it is verified. If so, and since truth involves the relations of objects to thought, it must follow that the making of truth implies a making of reality.

The individualism and plasticity inherent in these views met a storm of protest. Indeed, Peirce not only repudiated these extensions of pragmatism, but went so far as to rename his original view pragmaticism. Even John Dewey, although indebted to these thinkers and popularly classified with the pragmatists,

has been careful to indicate his differences from them by labelling his own views instrumentalism and, later, experimentalism. Confronted with problems arising out of a precarious universe, man seeks to solve them by inquiry, by gaining control over the contingent factors involved. After forming a conception of how this adaptation might be made, he acts upon it *experimentally* after the manner of science to see whether the consequences which flow from action bear out his anticipation. Or, this is an instance of *instrumentalism* if one employs biological language and emphasizes the rôle of mind or intellect as the tool of adaptation.

In either event, the basic realism of Dewey's pragmatism should be noted. Truth is admittedly a matter of correspondence between belief or thought and the objects or facts to which they refer. Correspondence, however, depends, not on perception, but on the successful working out of some overt alteration of physical circumstances, the outcome of which will test the correspondence between fact and idea. Truth as workability or success is measured, not "in so far forth" as the outcome is satisfying, as indiscriminating followers of James held, but by the extent to which it leads toward and corresponds with the results anticipated. Furthermore, verification so described is so obviously predicated on the realistic character of the precarious in existence that Dewey must be dissociated from Schiller's conception that making truth implies the making of reality itself.

Since activism (*q.v.*) is the essence of the various interpretations of pragmatism, it is easy to understand how this philosophy has come to undergird the activity program of progressive education. Activity, pragmatically speaking, is not undertaken on its own account or because it is merely developmental, but rather because it has a unique function to perform in inquiry, whether that inquiry is carried on in the laboratory or the school-room. Because the demand for action grows out of inquiry into an indeterminate situation, the problem method is preeminently the pragmatic method of classroom instruction.

Moreover, pragmatism has supported emphasis on the employment of interest in learning because the pragmatic test of truth is, in some sense or other, affected by the interest

or purpose of the investigator or learner. But it will make considerable difference here whether one measures the "success" of such an educational practice from the point of view of James or Dewey. In the former, a much more subjective view of studies is likely to prevail, while in the latter, there is a more objective standard against which to judge. Objectivity involves here both the physical and social for Dewey; truth must be measured not only in the pragmatic correspondence of idea and fact, but also in a way that is public for all to see.

Pragmatism, especially for Dewey, thus has definitely democratic implications. Experience from one situation must be made available for understanding subsequent ones; a maximum amount of sharing of experience must be encouraged between individuals and groups. Freedom for individuality is a necessary concomitant of pragmatic education because the experimental approach to a precarious universe will more likely be successful where there is an abundant variety of controls suggested. Creative education will also find support in pragmatism but again one must distinguish carefully between Dewey's conception of contriving to adjust means to ends and Schiller's conception of creating reality itself.

Neither the emphasis on freedom or creativity points to a disregard of tradition. The culture of the past enters the curriculum, not as an end in itself, but because it is instrumental in the solution of some contemporary problem. It is these problems, furthermore, out of which the aims of instruction arise. Education in general has no aims; pragmatically, only such as teachers, parents, and pupils have aims. Moreover, these educational aims are instrumental to nothing outside of the educational process; in fact, education is subordinate to nothing save more education.

The chief criticism directed at pragmatism as a philosophy of education is that it is only a method. That it elevates method to primacy may be admitted at once. Yet this very fact has implications for a world view. As already indicated, it implies a precarious universe, a world "with the lid off," as James so appropriately described it. Such a world is dynamic and pluralistic. Its ethics, like its empiricism, is thoroughly naturalistic.

Though it looks askance at the transcendental, it is not irreligious (James, *Varieties of Religious Experience*; Dewey, *A Common Faith*) and is positively moral since all conscious education involves preferences and the formation of fundamental social attitudes. J.S.B.

PRECEPTORIAL SYSTEM. The preceptorial system varies in meaning among the few colleges which use the term. Colgate University, for instance, successfully uses preceptors for individual conferences an hour a week with freshmen. Elsewhere the term is occasionally used also to refer to other individual instruction or advising. The system is best known for, and therefore best defined by, its use at Princeton University. As inaugurated there under the leadership of Woodrow Wilson about 1905, it provided that classes would meet only twice a week instead of five times a week with an informal conference of half a dozen students and a preceptor replacing the other three meetings. Fifty new members were added to the faculty at one time in order to operate the plan. The system was successful from the start and was perhaps the first marked step by an American college toward making undergraduate instruction informal and individualized. It has also supplied precedent for tutors, independent study plans, honors seminars, and quiz sections, as well as for the abandoning of the traditional professional ideal of aloofness. To a large extent it eliminated the disadvantages of both large classes and very small classes. While it usually retains most of the disadvantages of short-term, "academic" courses, its only apparent inherent defect is its failure to provide truly individualized con-

ferences. (See LIBERAL ARTS COLLEGE: TUTORIAL INSTRUCTION.) M.G.F.

PRECOCIOUS CHILDREN—See GIFTED CHILDREN, EDUCATION OF.

PRE-DELINQUENT. A child whose social activities are beginning to show early signs of lack of respect for properly constituted authority or for the property and personal rights of others but whose behavior has not yet been adjudged delinquent by a Juvenile Court. Such a child frequently feels a lack of affection, status, and success. These unsatisfied and rejected feelings make him an easy victim of a poor social environment or of unscrupulous individuals.

The use of the term pre-delinquent has been objected to because of the implication that these children are doomed to a life of delinquency and crime. One large school system went so far as to organize a series of pre-delinquency classes for those pupils whose maladjustments were becoming increasingly serious. Changing the name of these classes to adjustment classes reflected a change in the attitude of the administrators and teachers and suggested a positive rather than a negative educational program. The term has been criticized on the further ground that it has little value as a means of describing or classifying children. (See JUVENILE DELINQUENTS.)

M.S.Q.

PREDICTION OF SUCCESS. Guidance (q.v.) is one of the most acute problems of the modern school, and any sound guidance program is conditioned upon the ability to forecast the future. Various aspects of guidance make it important to be able to predict academic achievement, vocational success, and the successful adjustment to personal and social situations.

In education, the prediction of success means that an individual is measured in a trait which can be measured, and that from his score or rating in this trait is predicted the most probable degree to which he possesses another trait that is not readily measurable, or that cannot or should not be measured. Thus we may administer a scholastic aptitude test to high school seniors and use their scores on this test as a means of predicting their ability to succeed at college.

The basis for the prediction is the degree of

PREDICTION OF SUCCESS

relationship between measures of the two traits. The closer the relationship—that is, the higher the correlation (*q.v.*)—the more accurate the prediction. Thus if the correlation between students' scores on scholastic aptitude tests and their success at college is high, the scholastic aptitude scores are a better basis for prediction than they would be if the correlation were low. The closeness of relationship between two traits is determined by the extent to which the individuals at a given level in one trait vary in the other trait. The relationship is close if all students who receive low scores on one trait also get low scores on the second trait; the relationship is far from close if those students who get low scores on one trait have a wide distribution of scores in the second trait. In fact, the actual prediction procedure is in terms of that variation—the *error of estimate*.

The error of estimate is the standard deviation of the individuals in one trait who are at a given level in the other trait. Although this variation is not the same for all levels of one trait, one value of it is computed—an average error of estimate—and used for all predictions for the two traits involved. The formula for the standard error of estimate is $\sigma(\text{est. } Y) = \sigma\sqrt{1-r^2}$. In other words, if on the basis of an individual's score on Trait X we predict his score in Trait Y, that prediction is in such terms as: the chances are 68 in 100 that his actual score in Y will be within $\pm 1 \sigma$ est. of his estimated score; the chances will be 95 in 100 that his actual score in Y will be within 2σ est. of his estimated score.

In education, as in other phases of life, prediction is usually improved by using more than one factor as the basis of prediction. There is little reason for using the students' scores on scholastic aptitude tests as the sole basis for predicting college success when such other factors as the students' high school record and intelligence test ratings are also available. The scores on two or more tests may be used as a combined basis for prediction by employing the statistical techniques of multiple correlation and multiple regression equations. It is possible to determine by statistical procedures what optimum weights should be allowed for the various factors; sometimes all factors should receive equal

weights, while in other instances the accuracy of prediction can be improved by allowing some factors much more weight than others. Afterward, *critical scores* may be determined which represent the minimum scores likely to be associated with success in the area where the predictions are made. Common uses for such critical scores are for admission to college and for eligibility to employment in Civil Service.

One of the safest generalizations that can be made regarding the present status of prediction is that it is subject to a considerable measure of error. Prognosis is always in terms of probabilities, never in terms of certainties. This is due to errors in the measures of success available, as well as in the instruments of prediction employed. For example, success in school is measured commonly in terms of school marks, which are notoriously unreliable, and vocational success is determined by salary earned or by the judgment of the employer, both of somewhat doubtful validity. Criteria for success in personal and social adjustments probably are subject to even greater error. Chance errors always tend to reduce the coefficients of correlation obtained.

It is no doubt partly because these errors are not constant that predictions vary from school to school, from subject to subject, and from student to student. Standards vary so widely among schools that a student may fail completely in one and succeed in another. It is well known that intelligence tests predict success better in reading and arithmetic than in handwriting and physical education. It also seems possible to predict the achievement of students at the extremes of the distribution more accurately than the achievement of those near the center.

It is always easier to hit a big target than a small one, and particularly so with imperfect instruments. This explains why it is easier to predict the average marks of students in college or secondary school than it is to predict marks in the separate subjects, and why it is always especially difficult to predict the achievement of a particular individual in a given situation. Factors may afford satisfactory predictions of the average performance of groups and yet be most hazardous for predicting individual achievement. Further research is greatly needed upon differential predictions, that is, upon ability pat-

terms associated with achievement in various areas.

Prediction as a statistical procedure is in terms of the average, not of the individual student. The prediction for individuals is often much less accurate than the accuracy of prediction for the average. Thus the statistician, given a group of students who have identical scores on scholastic aptitude tests, high school records of equal merit, and equal ratings on intelligence tests, can predict fairly accurately how well these students, as a group, will fare at college. The registrar, on the other hand, using the same measures as the basis for selecting prospective freshmen, cannot be so accurate in predicting the college success of an individual applicant for college entrance. A great many factors, aside from purely statistical ones, complicate the problem of prediction for the individual. The college success of a given individual may be different from that predicted for him for such a reason as a change in the family finances, with the resultant need for carrying a part-time job while he goes to college. The statistician is confident that not all students will fall in love, contract influenza, meet an inspiring teacher, or find a personal goal that makes college work increasingly significant. The registrar and the dean, dealing with individual students, cannot be so certain that such factors as these will not destroy the accuracy of their predictions.

Education is no exception to the general rule that the only way to predict the future is by the past. It is not surprising, therefore, that the best basis for predicting achievement on any academic level is the student's record to date. Marks in the elementary school usually give the best single basis for predicting success in the secondary school, just as marks in the secondary school usually do for college. In like manner, as a rule, the best basis for predicting achievement in advanced courses in any subject is the earlier record in that subject. This also seems to be true for graduate and professional schools, as well as to a considerable extent for life outside. (See PROGNOSTIC TEST.) C.C.R.

PREFECT PERIOD—See HOME ROOM.

PREPARATORY SCHOOLS. The term *preparatory* when applied to schools usually refers to preparation for college. All cosmopolitan or non-specialized secondary schools have at least one curriculum designed to prepare the students for college. But only those schools that exist primarily for this purpose are usually referred to as preparatory schools. They are chiefly private schools, and many of them, particularly those in the New England and Middle Atlantic states, stem from the colonial grammar school or are the outgrowth of the academy movement of the 19th century. Some originated as an adjunct to a college, and serve primarily as a tutoring school for that college. The large majority, however, are independent and privately controlled and prepare for admission to any college.

The tradition associated with a few of the better known preparatory schools is at least as strong as that of many colleges. Waiting lists for enrollment are not uncommon, and membership in families of previous graduates is at least a decided asset, if not almost a prerequisite, for admission to a few of the more exclusive schools.

Although most preparatory schools are for boys only, some exist for girls, and a small number are coeducational. (See SECONDARY EDUCATION.) J.B.

PREPARENTAL EDUCATION. Education designed specifically to prepare young people for future parenthood. Although many kinds of education make indirect contributions to this end, the term *Preparental Education* is usually applied to instruction concerning the characteristics and needs of children, and parent-child relationships. Such instruction may be given in specialized courses which deal also with other aspects of home making and family life (See FAMILY LIFE, EDUCATION FOR).

One of the most important features of preparental education is the provision of opportunities for actual contacts with small children to supplement theoretical instruction on child development. Pioneer work in this connection was done by the Merrill-Palmer School. Several colleges and universities and

a few high schools maintain nursery schools which serve as laboratories for their students; in most other institutions which offer preparental instruction, the cooperation of the independent nursery schools, elementary schools, day nurseries, clinics, settlement houses, private homes, etc., is secured. Sometimes there are demonstration cottages in which the care of a baby or small child can be taught. Students contact with children may include only the demonstration of child care techniques by an instructor, or it may include directed observation and note-taking by the students, or actual experience in caring for and working with the children.

At the college level, preparental education in its more intensive form is apt to be restricted to students (usually women) who are majoring in such fields as home economics, education, or child psychology. Training at the high-school level and earlier, where the curriculum and the students' interests are usually less specialized, has the advantage of reaching more students, including those who marry at an early age and others who do not go on to college. The extension of preparental education to young men and boys has been carried out by a few colleges and high schools, though much remains to be done in this direction. Non-academic agencies which offer preparental instruction include the YMCA and YWCA and the 4-H clubs. (See also EDUCATION FOR FAMILY LIFE, PARENTAL EDUCATION.)

PRESCHOOL EDUCATION. The educational experiences of the child from birth to entrance into the first grade of elementary school.

In its wider sense this is a recognition of the fact that the child is receiving an informal education before he begins to learn to read and write and study arithmetic. This education comes from contacts with adults and children both within and without the family

and from actual experience in living.

In its narrower sense this term is used to designate nursery school, kindergarten, or kindergarten extension experience. (See NURSERY SCHOOL; KINDERGARTEN; KINDERGARTEN EXTENSION.)

PRE-SERVICE TEACHER EDUCATION—See TEACHER EDUCATION.

PRETEST. A *pretest* (also called *initial test*) is a test designed to gauge the pupil's knowledge before he begins the study of a new topic or unit of work. Pretesting enables the teacher to determine the equipment which each pupil brings to the study of the topic and the range of individual differences in his class. The pretest thus helps the teacher to pitch his instruction at the level shown by the class as a whole, and to discover those pupils whose previous knowledge is below the class average so that he may provide the necessary individual assistance. Special projects may be designed for those pupils whose pretest results indicate advanced standing.

Pretests are used at the beginning of an experiment to determine the status of the group at the outset. Improvement is then measured by increases in the scores on the equivalent tests used at the end of the experiment. J.J.

PREVIEW COURSES. Preview courses were organized at the junior high school level to assist pupils in an exploration of interest and abilities. In the field of language, for example, these courses consist of short units in Latin, French, Spanish, German, or Italian. The pupil is introduced to various languages that he may choose more intelligently a language for further study. (See GENERAL LANGUAGE.)

Likewise, courses are organized in the field of industrial arts dealing with such activities as printing, electricity, woodworking, sheet metalworking, etc. Such courses are often designated as exploratory or broadening and finding courses. They operate from nine to eighteen weeks. In the science field, "general science" is often considered a preview course since it gives a general orientation to the entire field of science. Following such

preview courses the pupil is allowed to select a field for further study. W.H.B.

PREVOCATIONAL EDUCATION.

Various forms of practical arts education such as industrial arts, general business education (e.g., typewriting and bookkeeping), general home economics (e.g., introductory courses given in junior high schools), and general agricultural education (e.g., school gardening) are often mentioned as forms of *prevocational education*. These activities are prevocational in that they provide exploratory experiences in representative forms of general education before vocational choices must be made, before vocational education is undertaken, or before persons must enter employment—hence prevocational.

These experiences and others of a similar nature have a prevocational value in the sense that they add to the preparation for a specific vocation, as premedical training does for physicians and as prelegal training does for lawyers.

Claims as to the prevocational value of representative materials, tools, processes, and techniques used by young people in the world of work must be restricted to those for which value can be proved. Experience has shown that the conditions under which so-called prevocational education is given in schools are sometimes very different from those found in actual practice in the vocations themselves. (See VOCATIONAL EDUCATION.) F.T.S.

PRIMARY LEARNING—See LEARNING, SIMULTANEOUS.

PRINCIPAL, SCHOOL. Elementary School Principal. The title of principal of an elementary school was first used in New York and Buffalo about the middle of the 19th century. These early principals were little more than head teachers and assumed few duties of administration and supervision. The importance of the office developed with the rapid increase in school enrollment which made necessary large elementary school buildings and increased the problem of accounting and monitorial work incident to the graded school system. The principal also assumed more supervisory duties and in some cases became the chief supervisor of his building.

The training of elementary school prin-

cipals has increased gradually since the early period until now most of them in the large schools hold bachelor's or master's degrees. Studies show that in 1932 about sixty per cent of men elementary school principals and forty per cent of women had more than four years of college training.

Elementary school principals are frequently classed as supervising principals (*q.v.*) and teaching principals. The former devote the major portion of their time to the supervision and administration of the school. This position is more commonly found in the larger schools than in the smaller ones. The teaching principal devotes the larger part of his time to teaching and a smaller part to supervision and administration. Guidance is now generally considered as the function of the elementary school principal.

In 1940-41 the salaries of elementary school principals ranged from an average of \$1,878 for supervising principals in school system in cities of 2,500 to 5,000 population to \$4,621 in school systems of over 100,000 population.⁴ In general the salaries of principals vary with the amount of training and experience and the size of the school system.

Secondary School Principal. The position of secondary school principal is an outgrowth of the position of master of the Latin Grammar Schools and the academy of an earlier day. The modern high school principalship was developed during the period from about 1820 to 1860, and roughly paralleled the period of the establishment of the superintendency. In many cases the superintendent of schools took charge of the secondary schools, and in some he served as principal. As the secondary schools developed, the principalship emerged as a distinct position apart from the superintendency. The secondary school principal assumed more administrative responsibility and devoted less time to teaching. He also assumed large supervisory responsibilities in his school.

The qualifications of high school principals are usually higher than those of classroom teachers; in addition to training in teaching they usually have special administrative and supervisory training. In many of the large high schools and in the secondary schools accredited by the North Central Association they are required to have the master's degree or its equivalent. In 1931 the

PRINCIPAL, SUPERVISING

National Survey of Secondary Education reported that in communities of 5,000 to 500,000 population, forty-four per cent of the high school principals held bachelor's degrees, forty-two per cent, master's degrees, 1 per cent doctor's degrees, and thirteen per cent, no degree.¹

The high school principals are usually selected by the superintendent of schools and appointed by the board of education. In addition to their educational qualifications, they are usually persons who have had experience as teachers. The tendency to require teaching experience has been a growing one and is now generally a requisite for appointment.

In 1940-41 the median salary of high school principals in school systems in cities of 2,500 to 5,000 population was \$2,136; in cities of 5,000 to 10,000 population, \$2,596; in cities of 10,000 to 30,000 population, \$3,303; in cities of 30,000 to 100,000 population \$4,806.⁴ The size of the school system with its attendant responsibilities is an important factor in the determination of salaries. It is also true that principals in the larger schools are better prepared and have had more experience than those in the smaller ones.

With respect to the principal's duties and responsibilities, both practice and the judgment of administrators show a wide variation in the distribution of time and functions. The National Survey of Secondary Education shows that the average percentage of time of principals of schools in communities of 100,000 population and over devoted to the following activities is: administrative, 40.2 per cent; clerical, 9.5 per cent; public relations, 8.5 per cent; research, 7.2 per cent; supervisory, 26.6 per cent; teaching 3.1 per cent; guidance, 10 per cent; and other types of activities, 3.3 per cent.¹

In the small school systems the high school principal devotes much time to teaching, and in addition carries on the clerical activities of record keeping, schedule making, discipline, etc. The major administrative responsibilities for the schools are assumed by the superintendent.

PRINCIPAL, SUPERVISING. The Seventh Yearbook of the Department of Elementary School Principals traces the development of the elementary school principalship through five stages: the one teacher, the head teacher, the teaching principal, the building principal, and the supervising principal. The duties of the first three are largely teaching; those of the fourth, administration; and those of the fifth supervision. The supervising principal is a well trained professional worker who is freed from teaching and clerical duties in order that he may devote the major portion of his time to the improvement of instruction.¹

In 1928 the median school under a supervising principal enrolled more than 600 pupils and most frequently included grades from the kindergarten through the sixth. The median number of years of college training was 4.13 and the median experience 23.84 years, 10.14 of which were spent as a principal.¹

In 1938, a study of some 12,000 principals showed that about one-third held full-time positions and were regarded as supervising principals, somewhat more than one-half were teaching principals, and about ten per cent were divided between principals with assistants and principals of several schools. In cities of 2,500 to 10,000 population about 90 per cent were teaching principals, whereas in cities of over 100,000 population 70 per cent were supervising principals. About one-third of the elementary school principals were men and two-thirds women, but the proportion of men was larger in the large cities and smaller in the small ones.³

The salaries of supervising principals in elementary schools were generally higher than those of teaching principals. In 1940-41

median salaries of supervising principals in cities of 2,500 to 30,000 ranged from \$1,878 to \$2,220; in cities of 30,000 to 100,000 \$2,470; and in cities of over 100,000, 3,420.² (See ADMINISTRATION, SCHOOL; PRINCIPAL; SUPERVISION OF INSTRUCTION.) W.C.R.

PRINT SCRIPT WRITING—See HANDWRITING, TEACHING OF.

PRISON SCHOOL. In a majority of the prisons throughout the United States there may be found what is called a prison school, although there are a few prisons wherein no educational activities of any kind exist. Where there are no educational activities it is common to find a large number of the prisoners wholly idle. Occasionally a few of them may do a certain amount of work each day, and it is not unusual in such places to find some inmates assigned to administrative duties which give them an opportunity to carry on a wide variety of objectionable activities for the benefit of themselves and their personal friends.

Now and then prison officials (often as a result of stimulation by prison chaplains) try to combat the evil effects of idleness by the establishment of prison schools. In such cases the officials are more concerned, if not altogether, with occupying the time of their prisoners than with bringing them educational benefits. They know that the busy prisoner is less likely to be troublesome. The direction of such prison schools is usually by the chaplain (or occasionally by a prisoner or an employee) while the teachers are usually prisoners. As a rule the organization of the school aims to follow traditional lines. Objectives are obscure. Inmate teachers are poorly prepared and lacking in competence. There is a meager supply of materials and equipment. Old discarded textbooks are used. There may or may not be a prison library containing few if any useful books.

Some correspondence or cell study courses may be included, usually not. Generally, the program will be restricted to standard academic subjects. Sometimes only the illiterate prisoners are admitted, although some prisoners may be students in the school for the purpose of reviewing elementary subjects. The school may be located in some part or parts of the prison unsuitable for other purposes, and, therefore, for school purposes.

During the past twenty-five years, and particularly since 1930, there has been a marked and rapid change in the organization and development of prison schools. The prison riots of the latter part of the decade 1920-30, gave considerable impetus to a critical examination of American penological practices, which a few years earlier had been brought into the limelight as a result of the work of Thomas Mott Osborne and others. Perhaps Osborne's efforts may be considered to have been the birth of twentieth century modernization of viewpoint and method in penology. During the years 1927-28 Mr. Austin MacCormick visited all prisons and reformatories for men and women (State, Federal, Army, Navy) in the United States with three exceptions. As a result his book "The Education of Adult Prisoners: A Survey and a Program" was published by The National Society of Penal Information in 1931. This book became a potent influence in stimulating the development of modernized and more effective educational programs in penal institutions everywhere. Since then the type of prison school already described here has begun to disappear. In its stead there are now many prison schools operated for the primary purpose of making available to prisoners the benefits to be derived from purposeful education.

Large prison systems such as the Federal system and the New York State Department of Correction employ Directors of Education and staffs for the purpose of centrally directing all education activities of the system, including the training of personnel. In such systems usually may be found competent, professionally trained institutional directors of education, supervisors, librarians, teachers, and vocational instructors; broad and comprehensive curricula; fairly adequate supplies and equipment and up-to-date school and shop buildings. Also, there are excellent libraries, correspondence courses, cell study.

PRIZES

courses, vocational and related vocational classes, directed recreation, physical and health education, mental hygiene education, music and art classes, guidance service, and employment service—in fact, all of the constructive and purposeful educational activities one would expect to find incorporated in a progressive educational program. Between the poorest and best prison schools heretofore described are those of the majority which range from fair through average to good in organization, offering, personnel, supplies and equipment. Today the trend is definitely toward the improvement of the prison school. Some of the best educational opportunities available below the college level in the country may upon rare occasions be found in a penal institution. The penal institutions of New York State, Wisconsin, Michigan, and California have excellent comprehensive educational programs while numerous other states are not far behind. The prison schools of the Federal system are also excellent. (See CORRECTIONAL EDUCATION, REFORMATORY EDUCATION.) W.M.W.

PRIZES. The use of prizes and awards as an incentive for improvement is an educational practice with a history almost as long as that of education itself. Prizes and awards have taken many forms: they have been as tangible as gold medals and sweaters, as symbolic as the piece of ribbon worn on the lapel, and as immaterial as the right to call oneself a Central High School Scholar. They are used in kindergarten classes and are found in graduate schools. That prizes and awards have been employed for so long a period of time and at so many different levels of education is evidence enough of the faith which teachers have in their appeal as incentives.

In modern educational theory, the use of prizes does not enjoy the high prestige that its continued use in our schools should imply. Although their use does offer an immediate and an obvious reward for effort and achievement—a reward that may stimulate many students—objection has been raised to the extrinsic motivation on which reliance is placed. To some critics, the use of prizes seems to imply that the work is not worth doing for its own sake. If the students know what they are doing and why they do it, is it necessary to add the incentive of a prize

for those who do it best? These critics see in the prize a confession by the teacher that the work has so little significance to students that only the prospect of winning a prize affords the incentive to continued progress.

Teachers have objected to prizes because they tend to stimulate only the best students in the class without improving the work of the other students who may need the added incentive. When an announcement is made that blue ribbons will be awarded to all students who maintain an average of at least 85 per cent in all subjects, the mediocre student soon learns that there is so little hope of his receiving the award that his is only the spectator's interest in a race. The practice has grown up therefore of awarding prizes for outstanding improvement as well as for outstanding achievement.

From the mental hygiene point of view, prizes and awards have been criticized because of the attendant emphasis on individual competition rather than on cooperation, and because of the emotional problems that may be accentuated by the stress of competition and the sting of failure. If the prize is given to the pupil who writes the best essay or who paints the best picture, the pupil may see little reason for sharing his experiences with his classmates or for helping them to improve. For this reason, awards and prizes are often awarded to groups rather than to individuals; thus the attendance banner may go to the class that has the best attendance. Even this modification may not solve the problem, for group pressure may compel a child to come to school on days when his cold should keep him at home. Other schools attempt to reduce the disadvantages of prizes and awards by increasing the number of students who may earn them and by extending the list of traits in which excellence is recognized. Thus all students who meet a given standard may have the satisfaction of seeing their names on the Honor Roll or the Dean's List. Recognition may be given for such intangible traits as initiative and service to others as well as for such academic qualities as success in passing Spanish tests.

It is difficult to justify the use of awards as a subterfuge for bribery. The high school and college student should see in the minimum academic requirement set for eligibility for an N.Y.A. position a means of restricting

these positions to students who can fill them without endangering their status as successful students rather than a monetary reward for doing the homework regularly. It is difficult, too, to do more than sympathize with the teacher who feels compelled to hold before the class bully the prospect of appointment to a monitorial position if he will stop molesting the younger pupils.

It is nevertheless true that many schools employ prizes and awards without having any of the dire results which are so easily anticipated. In such schools there are usually wholesome pupil-teacher relationships, adequate attention to the students' personality needs, and ample opportunities for all students to understand the significance of the activities in which they engage and to experience the thrill of success and social recognition.

PROBABLE ERROR — See **RELIABILITY**.

PROBATIONARY TEACHER. In several states and a number of cities, a teacher who has served conditionally in a school system for a stated period of years and has been reappointed for the following year, has a stated legal right to continuous employment during efficient service. The period of conditional service is called a *probationary period*; and the teacher while serving thus is known as a *probationary teacher*.

The period of probationary service varies in the cities and states having tenure laws, the most common maxima being from two to five years. In Ohio, for example, except in certain small communities, a teacher may be placed on tenure after serving from one to five years on probation. (See **TENURE**.)

As a rule, the probationary teacher carries a regular teaching and extracurricular program, although he is usually supervised more

closely than is the teacher who has attained tenure. The basic distinction between a probationary teacher and the teacher on tenure is that the probationary teacher may be released by the school at the expiration of his contract without the necessity for the filing of charges and the holding of a hearing, both of which are required when a teacher on tenure is dismissed. Some school systems give the probationary teacher an annual report which includes an evaluation of his ability and an enumeration of the respects in which further improvement is expected. In some schools, if a probationary teacher is not reappointed, he may be given a statement of the reasons for his non-reappointment, even though such a statement is not required by law.

The practice of regarding the newly-appointed teacher as a probationary teacher is a means of safeguarding the school system against granting tenure to teachers who seemed to be persons of promise when they were appointed but whose performance on the job did not reach the high level demanded by the school system. On the other hand, setting a definite time limit to the probationary period protects the teacher from the uncertainty attendant upon an unpredictable delay in his attaining tenure. By learning within the first few years of his association with the school that he will not be accepted as a member of the permanent staff, the teacher can make the necessary personal and professional adjustments with less hardship than if he were released after several years of service at that school.

PROBLEM METHOD. The problem method refers to the use of the problem-solving procedure in organizing classroom activities. To use such a procedure it is necessary to have a problem as the challenge or stimulus for learning. A problem may be defined as some difficulty, perplexity, or doubt requiring solution and for which no ready answer can be given. In everyday life we are constantly dealing with problems that stimulate or challenge us to find a solution. For such situations no ready-made "book answers" are available. To solve them we

are stimulated to search, to inquire, to look for necessary materials, and to consider critically all factors bearing upon the problem in order to reach a satisfactory solution. Such activity involves reflective thinking and other experiences vital to real learning. The use of the problem method in school is an attempt to realize the values of such experience. It should be clear that the success of the problem method depends largely upon the nature of the problems chosen and the challenge they offer to the pupils.

There are two distinct ways in which problem-solving is ordinarily used by teachers. One is to make use of problems incidentally in connection with the other work of a course or unit, chiefly to improve comprehension or to perfect some ability or skill. The other is to organize a course or units as a series of problems to be solved. A Problems of Democracy course, for instance, may be organized in terms of such problems as The Rights of Minorities and the Conflicts between Capital and Labor. While the latter provides the possibility of more nearly approximating life situations, and therefore gives valuable training, many educators contend much that needs to be learned in school, especially in so-called "skill subjects" like arithmetic and foreign languages, can be learned more effectively through direct teaching and learning, supplemented by the use of problems for practical application. At the high school level, the problem-solving approach can be used most effectively in the natural and social sciences.

There are at least four essential steps in problem-solving, which may be described as follows: (1) recognition and statement of the problem, (2) inspection and proposal of a solution or solutions, (3) critical evaluation of and attempt to apply proposed solutions, and (4) verification of accepted solution. While these four steps are essential, seldom will they occur in precisely the preceding order. According to Dewey's illustrations of reflective thinking in problem-solving, one proposed solution after another is likely to be tried out and discarded before even the final and accepted solution is thought of. Under some circumstances the gathering of data may take some time before any proposals are forthcoming. For these reasons, some teachers have proposed the

following three step problem-solving procedure as a guide to effective training: (1) Introductory step—introduction and statement of problem—the challenge, (2) Developmental step—proposed solutions, gathering data, critical evaluations, formulation of conclusions, (3) Application or Summarization step—verification of results (if desired). The effectiveness of problem-solving depends much upon competent teacher guidance.

PROFESSIONAL APTITUDE TESTS.

The movement for vocational guidance (*q.v.*) which sprang up in the desire to help adolescent boys and girls to discover those occupations which are best adapted to their abilities has gradually been extended upwards. With the increasing number of students enrolled in institutions of higher education it became necessary to devise methods to advise students planning to enter professional schools and at the same time, because of pressure of numbers, it also became necessary for these schools to adopt some standards of selection. From the point of view of students it was considered desirable to protect them against the "disappointment, disillusionment, and waste" of failure. From the point of view of the professional schools it was equally desirable to secure students who were most likely to succeed in their studies.

The development of professional aptitude tests began soon after World War I—first for admission to law schools, then to engineering schools, and later to schools of medicine. Only in the field of medicine has the use of

PROFESSIONALIZED SUBJECT MATTER

aptitude tests been continuous; in the other two fields their history has been sporadic, perhaps because the full support and cooperation of the respective professional organizations have been lacking. In the case of medicine the Medical Aptitude Test, developed by Dr. F. A. Moss, has been used since 1929 under the sponsorship of the Association of American Medical Colleges. In law, only in the Schools of Law at Columbia and Yale Universities has the use of aptitude tests had a continuous history over a period of years, and in engineering, only Stevens Institute of Technology has had similar extended experience with aptitude tests. Where professional aptitude tests have been used for a length of time, the records have shown that, if properly constructed, they are effective in reducing the number of failures in the respective courses. The score attained by a candidate in the aptitude tests indicates only his chances of success in the particular professional course to which he is admitted; it is no indication of success in the practice of a profession.

In the last few years experiments have been under way to construct aptitude tests in other fields of professional study—dentistry, pharmacy, and nursing. Efforts to devise prognostic tests of ability in teaching have so far failed. In the field of graduate studies the Carnegie Foundation for the Advancement of Teaching, in cooperation with a large number of colleges and universities, has developed the Graduate Record Examination as a test of the aptitudes of students in the various fields of graduate study. I.L.K.

P. SANDIFORD, and others, *Forecasting Teaching Ability*, Bulletin No. 8 (University of Toronto, Department of Education Research, Toronto, 1937).

PROFESSIONALIZED SUBJECT MATTER. "Professionalized subject matter" is the term used to describe courses that combine subject matter and methods of teaching the subject matter under discussion. Such a course results, for example, when a traditional course in science is combined with a course in methods of teaching science. A college course in American history would be

devoted to the subject matter of American history; a professionalized course in American history would present both the subject matter and methods of teaching American history.

With the growth of the normal schools and teachers colleges (*qq.v.*) came the issue of academic versus professional training. It was argued that anything in the way of subject matter needed in the equipment of the teacher should be incorporated as a basic part of the training program. As the normal schools developed they were more and more under the criticism that they did not provide a basic general education for their students. There was also a pedagogical development which called for a training program which would equip the teacher both academically and professionally. As normal schools developed into teachers colleges the pressures applied by accrediting agencies—which reflected the point of view of liberal arts education—great emphasis was placed upon professionalization of subject matter so that teachers might receive the fundamentals of a liberal education and, at the same time, acquire the necessary teaching skills.

Two examples stand out in the effort to professionalize courses. The first is in the field of mathematics where, especially for teachers in the elementary school, refresher courses in arithmetic are included in courses dealing with methods of teaching arithmetic. In the field of science there have been substantial professionalization courses combining both content and methods of teaching. This is especially true with respect to the training of elementary and junior high school teachers.

Those responsible for traditional subject-matter courses often oppose the professionalization of courses on the ground that it is impossible to combine in a single course both content and methods. Since teachers of college subjects have given relatively little attention to methods of teaching in the subjects for which they are responsible, they naturally do not accept readily a program of professionalization. The problem in teacher-education institutions is that of finding scholars who are skilled teachers and who also are competent to devote consideration to methods of teaching the subject to others.

There is wide variation in the curriculum of teacher-education institutions with respect

to professionalized subject matter. With the coming of the junior college as the first two of the four-year period of teacher-education institutions, wider interest has been shown in general education. Such "general education" courses are organized for the purpose of giving a broader survey in subject fields or areas. This makes it possible to defer "professionalized content," since the latter part of the training course is devoted to methods, thus freeing the earlier years for general education.

PROFILE GRAPH. A graphic representation of an individual's performance on a series of tests or a series of ratings of his personality traits. After the student has been given a series of tests and his raw scores have been converted into comparable scores by using standard scores or a table of norms (*q.v.*), the profile graph makes it possible for the teacher to depict all of these converted scores on a single graph. The subjects in which the student has been tested or the personality traits on which he has been rated are equally spaced along one of the coordinate axes of the graph, and the converted scores are indicated along the other axis. These points are then connected to form a *psychograph* or *trait profile*. Such a graph makes it possible for the teacher to see quickly how the student's achievement compares with that of the average child, and it also enables the teacher to see at a glance whether the child's abilities represent an even level of achievement or whether there are any special abilities or weaknesses in the various subjects and traits.

J.J.

PROGNOSIS—See PREDICTION OF SUCCESS; PROGNOSTIC TEST.

PROGNOSTIC TEST. A prognostic test is one designed to predict the pupil's ability to learn a specific school subject. The most widely used prognostic tests have been developed in secondary school mathematics and foreign languages; for example,

the *Orleans Algebra Prognosis Test* (World Book Co., New York), and the *Symonds Foreign Language Prognosis Test* (Teachers College, Columbia University). The *Metropolitan Readiness Test* (World Book Co., New York) is illustrative of the relatively few prognostic tests constructed for use with elementary school children.

In general, three techniques have been used in constructing prognostic tests: (1) The mental functions entering into the mastery of the particular subject are determined and a test is developed to measure these functions; (2) a series of sample lessons in the subject is presented to the pupil, each lesson being followed by a test to determine how much he has learned; (3) a test is administered to determine the pupil's knowledge in a given field before he begins formal study of the subject. These three approaches are concerned in large measure with the pupil's ability to master the content of a given subject. Success in any school subject, however, is influenced by a host of environmental and psychological factors which, of necessity, must be disregarded when constructing the prognostic test. The tests do not measure, for example, the quality of the pupil's study habits or the strength of his motivation for school success. As a consequence, the test by itself cannot predict perfectly future success in a given subject. In fact, correlations between scores on a prognostic test and academic success are usually about $+.50$ or $+.60$, much too low for accurate prediction of the level at which an individual may be expected to work.

Despite the weaknesses of prognostic tests, they are valuable in the guidance and placement of pupils. When used in conjunction with other measures of ability, such as intelligence tests, they give a better indication of future success in a specific subject than does the use of an intelligence test alone. Prognostic tests are, therefore, a useful device for reducing the wastefulness of school failure. Scores on prognostic tests may be used as a basis for classifying students so that those who are likely to experience difficulty in a particular subject may be put into a slow progress class, while other students who will probably learn much faster can be grouped in another class. Prognostic tests also increase the effectiveness of instruction by making it possible for the teacher to

PROGRAM, DAILY

diagnose student weaknesses and to plan appropriate remedial work at the beginning of the term's work. (See PREDICTION OF SUCCESS.) J.J.

PROGRAM, DAILY. As applied to a school or classroom the *daily program* is a time and work schedule of major activities, used to guide pupils and teachers each day that the school is in session. The program usually contains the time or period for each class to meet during the school day in each of the various subjects or areas of experience, and, sometimes, the periods for study, work, or other activities as well.

There has been a decided trend in elementary schools away from rigid adherence to a fixed daily program and toward one which is flexible and easily adapted to changing school conditions and needs. The following flexible daily program has been used successfully in small schools carrying large curriculum units.³

Opening period.—Varied activities and shared experiences, including news, reports, and observations.

Planning the day's activities.—Time enough to plan the enterprises for the day.

Work period.—A long period (60 to 75 minutes) for construction and art work, experiments, creative writing, or cooperative activities.

Relief period.—Length and frequency varying with the maturity of the children.

Physical education and health.—At least 20 minutes for learning games and discussing health problems.

Evaluation period.—Time enough to discuss and evaluate the forenoon's work.

Noon hour.—Lunch and recreation.

Practice in skills.—In various fields, such as reading, spelling, arithmetic, art and music, and creative expression.

Opportunity period.—Individualized work wherever children need help, as in handwriting, reading and speech, science, appreciation materials, and hobbies.

In a weekly program, class and other learning periods are distributed on a weekly basis. There is considerable variation in the time when class periods in different subjects come each day, but the program for any one day is like the program for the same day on preceding weeks. The accompanying table is an example of a fourth-grade weekly program.⁴

Begin	Minutes		Monday	Tuesday	Wednesday	Thursday	Friday
9:00	30	45	Music	Science and Health	Music		Language
9:30							
9:45	60	45	Arithmetic		Arithmetic		Arithmetic
10:30	15		Physical Education and Play				
10:45	75		Reading	Social Studies	Reading	Social Studies	Reading
12:00	60		Luncheon and Play Period				
1:00	60		Language	Reading	Social Studies	Reading	Social Studies
2:00							
	30		Writing	Writing or Music	Art	Language	Writing
2:30	15		Physical Education and Play				
2:45	30	45	Spelling	Language		Spelling	
3:15							
3:30	45	30	Art	Spelling	Writing	Science and Health	Art

PROGRESSIVE EDUCATION

The teacher should follow principles of program construction that have been developed scientifically, have been tried out experimentally, and have stood the test of repeated use. The following are examples of sound principles that meet these criteria:

A period of physical rest should immediately precede practice activities requiring steady muscular movements.

Younger children should have shorter but more frequent periods for class meetings than older children.

More time and longer periods should be devoted to subjects or areas of experience which are most important and which have the most thought content.

A part of the child's school time should be organized in terms of long periods for broad subject-matter fields as well as short periods for minor divisions of subject matter and the practice of specific skills.

It is desirable to merge or fuse related subjects, such as history, geography, and civics, or language, writing and spelling, so that the weekly time allotment to a given division of the work may be greater.

In making a program the teacher should follow certain clearly defined steps. He must collect the necessary information about the school, the pupils, the classroom, the curriculum, and the time. He must know the type of school organization, the number of pupils and their maturation levels, the room accommodations and instructional supplies available, the curriculum requirements and textbooks in use, the building time schedule, and any time allotments for various subjects which may be required.

When he has collected this information he is ready to plan the program. In this connection several questions arise: What type of program is desired? May any subjects or grades be combined for instruction time? How many weekly periods of determined length will be allotted each subject or activity field? Issues like these may be decided by local administrative policies and plans. In others, the teacher will be guided by approved principles of program-making, such as those listed above.

In preparing the program the classroom teacher should begin by entering on his program form the limits of time determined by the building time schedule. He is then ready

to schedule class groups in accordance with sound principles of program-making. He should work to secure the most effective sequence of classes and the best time for each subject. As the work nears completion the program should be checked for determining where improvements are possible. (See SCHEDULES, SCHOOL.) C.M.R.

PROGRESSIVE EDUCATION. The term Progressive Education took on its present defined status with the organization of the Progressive Education Association (*q.v.*) in 1918 under the leadership of Mr. Stanwood Cobb. The movement itself is, however, much older, as well as much broader and deeper.

It seems historically justifiable to say that this movement began with Rousseau (1712-1778) (*q.v.*) and the *Émile* (1762). But it was Pestalozzi (1745-1827) (*q.v.*), much influenced by Rousseau and the general humanitarian stirring of his day, who began the significant remaking of the school along the lines here under study. His influence was world-wide and reached America through many channels, in the remaking of arithmetic and geography, in the making of our graded schools (coming by way of Prussia especially through the work of Horace Mann), in Sheldon's "object lessons," and in the later influence of Herbart (1776-1841) and Froebel (1782-1852) (*qq.v.*), both of whom studied with Pestalozzi.

But "progressive education" as we now know it is mostly an American product, owing much to Francis W. Parker (1837-1902) and John Dewey (1859-) (*qq.v.*), with Stanley Hall (1846-1924) and others having a lesser share. Colonel Parker started the actual teaching along this line and stirred great interest, first at Quincy, Mass., and later in Chicago, particularly at the Cook County Normal School. John Dewey, partly through

"the Dewey School" (1896-1903) at the University of Chicago, but largely through his writings and university teaching at Chicago and Columbia, has furnished the philosophy of education on which the progressive education movement has mainly gone forward.

Progressive education is a movement, not a creed; but it seems possible to state its main features as follows:

1. It is the democratic movement brought into childhood. In a new sense and to a larger degree the child is to be respected as a person, and childhood is not to be used merely as means and preparation for a later adulthood. Also, while parents and teachers are to remain in control, they will seek to extend as far and as fast as possible the area, fixed by them, in which the child is allowed and encouraged to make decisions on his own, learning of course to give due consideration to the rights and feelings of others.

2. It holds that children and youth—all people in fact—learn what they live as they themselves accept it to live by; further, that they learn this in the degree that they live it or count it important to them; and finally that what they thus live and accept (i.e., learn) they incorporate at once into their behavior structure (as mind and character). Moreover, it holds that the organism acts as a working whole so that each instance of learning involves an interrelated complex of thinking, feeling, and movement.

3. Since the child thus learns what he lives, the school should aim to be a place where the best possible of good living prevails, the kind of living fit to be built into character. The school is not a place where all the pupils do is learn about living. Rather it is a place where living goes on, and should be judged in terms of how good that living is.

If a child follows thoughtless or selfish whims, or fails to put forth his best effort either in thinking or doing, or yields to conduct lower than he knows to be right, then, according to progressive education, that child is, to that extent, building a lower type of character than is desirable, and his school is, to that extent, failing in its duty. On the other hand, in the degree that the child lives up to his best in thinking, in considering others, in sticking to his task even though it proves at times tedious and hard, in holding

himself thus to duty, insofar as he lives these things and accepts them in his heart as his way of behaving, and as he continues to improve upon his standards as he grows older, that child is building—and inevitably so—a better type of character, and his school can know that it is succeeding.

4. Since man can truly be man only in associated living, it becomes the social duty of the school to help each child grow up to effective living within the social group. The child should increasingly embody in himself the best of the cultural inheritance, accept the democratic obligation to improve the standard of surrounding social life, and, if possible, learn ultimately to add to that inheritance. This means, in accordance with the preceding principle of learning, that the school must not only be itself an example of desirable associated living, but that it should, as the children grow older, continually increase their interactions with surrounding social life so that they may learn, under actual living conditions, what those social conditions are, and how to control and improve them.

5. These considerations make clear why the progressive school refuses the usual practice of putting first the acquisition of "subject-matter" in isolation from its living use, and why it prefers instead to aim at the building, through high quality present living, of dynamic characters which will learn and use knowledge and skills in and for life's broader and better purposes.

The progressive education movement in its most modern phase began, we may say, in the latter part of the 19th century but spread only slowly until the end of the second decade of the 20th century. Since then it has spread rapidly in America, both in the elementary school and in the theory and practice departments of teachers colleges. Its acceptance has been slower but still real in the secondary school, and still slower but increasingly present in the college. In the United States the most common name used in connection with it is the "activity program" (*q.v.*), while elsewhere the practice is often called the "project method" (*q.v.*).

At the first, the opponents of the movement claimed that as a method it was ineffective. However, carefully conducted studies seem to show that for teaching the so-called "tool subjects" it is at least as effective as

PROJECT METHOD

any alternative, while for activities involving initiative, creativeness, broadmindedness, tolerance, honesty, and the like, it is clearly superior. The "*Eight Year Study*" (q.v.) for example, found that students from "progressive" secondary schools surpassed their "controls" along all significant lines of college success.

PROJECT METHOD. The project method of teaching refers to the use of projects as a means of organizing learning activities. The term was first used in teaching in this country in the field of manual training as early as 1900 to designate practical problems which involved making or producing some product through physical activity, without much consideration of the importance of pupil purposing or planning, although pupil planning was used. The term was gradually adopted in such other fields as home economics and agriculture, which also deal with practical problems.

After 1900 under the influence of the new psychology there was a gradual adoption of the idea that the project should be a problem-solving learning activity in which the pupil had an opportunity to choose, plan, and direct his own activities. According to this philosophy whenever the learning actually approximated the nature of a real life-problem and was planned and carried out in a practical way by the learner, it was referred to as a

project. Thus, making a dress, constructing a piece of furniture, or raising chickens for market are examples of projects. The term "home project" came into vogue early to designate a pupil planned practical problem carried to completion at home.

A further change in the interpretation of the project came about as a result of a wider acceptance of the Dewey philosophy and the attempt of teachers to plan units of learning that would be significant wholes based upon life patterns. This newer point of view was first definitely set forth in 1918 by W. H. Kilpatrick of Teachers College, Columbia University, who characterized the project as a "wholehearted purposeful activity proceeding in a social environment." This new interpretation of a project as any "wholehearted purposeful activity" was an attempt to capitalize on the fact that purposing and interest are potent factors in learning. This interpretation opened the door to the use of the term for any learning activity that had the characteristics of "wholehearted purposeful activity." As a result, there followed a period of some five or ten years during which teachers applied the term to such a variety of learning activities that the term almost ceased to have any significance as a type of organized learning activity. However, there finally evolved from this period of trial and controversy an interpretation that retained the important characteristics of both points of view.

As now generally accepted, the project is conceived as a unit of purposeful learning activity involving a practical problem complete in itself, aimed at definitely attainable goals, and planned and carried out by the learner in a natural and life-like way. Some would specify further that the ends or goals should be definitely and objectively measurable. Some teachers and laymen refer to the immaterial product, if any, as the project, whereas the real significance of the term is embodied in the concept of the unified purposeful activities that produce the material product, since these are of vital concern in determining the learning outcomes.

Projects have been classified in various ways depending upon the purposes or goals. The most common classification provides for three types; namely, (1) material projects involving the production of some material or

PROJECTIVE TECHNIQUES

physical thing, (2) learning projects involving the attainment of some ability or skill, and (3) intellectual or problem projects involving the solution of some problem or difficulty to gain knowledge or information. To these some would add the esthetic project involving enjoyment and appreciation.

The values of the project method may be summed up briefly as follows. The project method rests soundly upon the psychology that functional knowledge, abilities, and traits of character result from active participation in solving problems or difficulties. Since the pupil selects the project, or at least willingly accepts it as his own, the project starts with a purpose which is the pupil's. He sees the project as a real undertaking related to life, complete in itself, with definite, desirable goals. Then the fact that the pupil can do his own planning and direct his own activity, gives freedom and lends further importance to the undertaking. The project method is of value also because it is a means of providing for individual differences.

To realize the values claimed for the project method, the proponents of the method advocate the following teaching steps: *Purposing*, which involves the choice of the project and determination of the goals (under teacher guidance); *Planning*, which involves the choice of what is to be done and how it is to be done; *Executing*, which consists of the actual learning experiences in carrying out the project; *Evaluating* (optional with some projects), which consists of evaluating the results in the light of the desired goals.

There are two ways in which teachers usually make use of projects. One is to organize a course or portions of it by projects. The other is to make use of projects as a part of some other plan to provide extra work or to take care of individual needs or interests. Many teachers use individual projects in their differentiated unit assignments. Group projects are also used for groups or a whole class.

There are certain limitations to the project method that teachers should be aware of if they are to use it effectively. The following are the most important limitations: (1) it is difficult to provide a well-rounded curriculum of projects, since systematic teacher organization is apt to vitiate the very purpose of the project method: (2) the project planned

curriculum is apt to leave large gaps in content and needed pupil experience; (3) there is danger of much unproductive activity, wasted time, and lack of much needed practice; (4) the project method fails to give the pupil a perspective of the logical and integrated organization of the content of different fields; knowledge gained, although vital, is fragmentary. (See also ACTIVITY PROGRAM, PROGRESSIVE EDUCATION.)

PROJECTIVE TECHNIQUES. Projective techniques are methods employed by psychologists and psychiatrists in the personality study of individuals, and in the treatment of emotional maladjustments. Through the use of standardized visual stimuli or materials, information which the individual may be unwilling or unable to communicate regarding his feelings and attitudes is disclosed. Many of the techniques may be used therapeutically to reveal to the individual the motivations for his behavior, and give him an opportunity to release such emotions as fear, anxiety, and hostility.

There are many varieties of projective techniques, the most common ones being painting; drawing; finger painting; clay modeling; use of play materials, such as dolls and puppets; dramatic representations of problem situations; Stern's cloud pictures; and the Rorschach ink blot method. (See RORSCHACH TEST.) While many of them have their widest application in the diagnosis and treatment of children's emotional disorders, some, such as the Rorschach method, have a wide application in all age groups, as one of the battery of techniques used to diagnose personality disorders.

The greatest danger in the use of projective techniques is that they appear simple to use and, therefore, invite their use by people inadequately trained to recognize and handle the emotional situations created. Further-

PROMOTION

more, there may be a tendency to misinterpret the results obtained or read into the subject's activity far more than it actually represents. The unskilled worker should be especially aware of the hazards of inducing individuals to reveal, unwittingly, material about themselves which may be provocative of guilt or anxiety feelings.

Clinically, the psychiatrist working with a child might employ a play situation to enable the child to release a handicapping emotion. For instance, a small child, showing adjustment difficulties symptomatic of his hostile feelings toward one of his parents, would be helped to gain awareness of his problem and release of hostility in a controlled situation through the re-enacting of one of his problem situations, using dolls as representations of the people involved.

The teacher who makes use of modifications of these techniques should avoid any interpretations, but may utilize free painting or drawing, without concern about technical end-results, to permit children to express feelings and release tensions. G.M.A.

PROMOTION. The American school system is organized on the assumption that the child will make normal age-grade-progress and will complete a grade of schooling in the course of one year of attendance at school. Thus the six-year olds are expected to be in the first grade, the seven-year-olds in the second grade, and so on up to the twenty-year olds who should be beginning their junior year at college and the twenty-one-year-olds who should be in their senior year at college. Deviations from normal age-grade progress may be in the direction of either *acceleration* (more than one grade is completed in one calendar year) or *retardation* (less than one grade is completed in one calendar year).

Although the extent of acceleration and retardation varies with the promotion policies of various school systems, by the time children reach the seventh grade a considerable minority—in some school systems even a majority—of the children have made other than the normal age-grade-progress. Some have taken less than six years to reach this grade, while others have taken longer to reach the same grade. The amount of acceleration is small; the amount of retardation much greater. In fact, in many school systems there

are more pupils who have been retarded one or more grades than there are pupils who have kept up with each succeeding grade without either acceleration or retardation.

Since American educators are so well aware of the wide differences in pupils' mental abilities and in rates of mental growth, it may be assumed that the prevalence of acceleration and retardation reflects their recognition of the influence that differences in the pupils' I.Q. have on the pupils' rate of grade progress. If this were indeed the explanation for deviations from normal age-grade progress, the extent of acceleration should be equal to that of retardation since the distribution of intelligence approximates that of the normal probability curve (*q.v.*) and the number of children who are above average in intelligence is about equal to those who are below average in intelligence. However, probably in no school system in the United States does the amount of acceleration equal the amount of retardation.

The small percentage of acceleration is explainable on several counts. First, many school systems consider it poor policy to have a child "skip a grade," and no provision is made for a pupil actually to do the work of more than one grade in one year. Second, some schools think it unwise to put a child in a class where the majority of the children are chronologically older than he. Third, the curriculum usually offers so little challenge or interest to bright children that their performance is often much below that expected of children of superior intelligence. The actual results these children produce, when taken as an isolated criterion, may not indicate that they merit acceleration. Acceleration, where it is practiced, is usually regarded as a reward for past outstanding achievement rather than as a means for bringing about the best future learning on the part of the student.

Retardation, on the other hand, is an accepted feature of most school systems. The practice of having failing students repeat the grade has been defended as a method of disciplining "lazy" pupils and stimulating them to work to capacity, as a means of providing better adjustment for immature children, as a way of making up work lost through absence, and as an assurance that school standards will be maintained.

Many are the factors which have been

PROMOTION

regarded as the causes of retardation. Among those attributed to the child himself are: lack of mental ability; physical handicaps and sensory defects that impair the effectiveness of learning; irregular attendance resulting from illness or other causes, with consequent inability to complete essential work; ineffective study and work habits; lack of application, sustained attention, and effort; inability to assume responsibility; personality maladjustments and conduct problems from which learning crises result; and specific disabilities in one or more of the tool subjects, especially reading, in the early grades.

The school has been held responsible for such conditions as overcrowding of classes, inadequate curricula and poor grade placement of curriculum materials, inadequate instruction owing to poor quality of teaching, lack of guidance, two or more grades housed in one room, and inadequate provision for individual differences among pupils.

Among the causes of retardation attributable to the home and the environment have been included parental indifference, low standards of living, broken homes, frequent transfers from school to school, and bad associates and companions.

Pupils who at the end of a term have not met the standards set for that term are "not promoted" to the next grade and therefore repeat the work of the same grade, often with the same teacher, the same teaching method, the same textbooks, and the same assignments, and are treated as though they had been newly promoted to that grade. Repeating a grade in this manner usually brings little or no improvement in achievement. Sometimes actual regression has been the result. Feelings of frustration, inferiority, and boredom are likely to arise, bringing with them maladjustment and problem behavior. Moreover, it has been found that when repeaters are treated as new pupils, and the time they spend repeating a grade is not used for remedial treatment at the point of their particular weaknesses, their achievement in the next grade is no better than that of others of similar age, ability, and achievement in the previous grade, who were promoted to the next grade without repeating a grade. Some educators nevertheless justify the practice of nonpromotion on the ground that repeaters serve as a warning to other children. There is no proof that repeaters do serve as a moti-

vating force. In any case, many educators frown upon a method which abuses the personality of one child for some expected gain to others. The number of children who have repeated one or more grades has decreased markedly since the turn of the century, when a survey of New York City schools showed an amount of repetition that was considered appallingly excessive. The decrease has been due not primarily to better teaching but to a change in the standards for promotion.

The policy of *conditional promotion* has been used widely as a substitute for nonpromotion, both in the elementary school and in the high school. Conditional promotion is meant to indicate to the pupil that he has not mastered adequately the work of the grade but that, all things considered, he can get along in the next grade provided he puts forth sufficient effort. It is therefore meant to serve as additional motivation since the threat is held over the child that if he does not do well at the beginning of the succeeding grade he will be demoted. Actually many—sometimes estimated at 50 per cent—of those who have been conditionally promoted are later demoted. This does not help the situation either from the point of view of emotional adjustment or of learning progress. It is possible too that the conditionally promoted pupils who are not later demoted would get along better if they did not have the fear of demotion constantly with them.

The problem of retardation has also been attacked through multiplying the number of grade divisions at which promotion and nonpromotion are regularly considered for each child. While each grade still covers a year of schooling, grades have been divided in many school systems into half-grades and even quarter-grades. Nonpromotion, under such schemes, requires the pupil to repeat the work of only part of a year. Since these schemes necessitate that all parts of each grade be maintained during each school term, they can be used only in schools that have a large population for each grade. Promotion on a quarterly basis, with terms consisting of ten weeks each, was established more than seventy-five years ago in St. Louis, and is still being used there. In fact, it is often called the *St. Louis Plan*. While it did have considerable vogue elsewhere for a time, during the past decade it has rarely been in use outside St. Louis.

Half-grades and semiannual promotions are sufficiently numerous throughout the United States for comparisons to be made with regard to grade progress under annual and under semiannual promotion schemes. In semiannual promotion schools, about twice as many (about 30 per cent) of the pupils have experienced nonpromotion during their elementary school career as have those in annual promotion schools; while in annual promotion schools the amount of time lost per retarded pupil is greater. Statistical evidence with regard to the comparative merits of the two systems is sufficiently inconclusive so that changes from annual to semiannual promotion and vice versa occur in a number of city systems every year. Certain systems have changed back and forth periodically. Nevertheless, at any one time more than three-quarters of all but the smallest cities are organized on a semiannual promotion basis. A number of them, however, seek to overcome the disadvantage to the children of having a different teacher every half-year by having those children who are promoted from the first-half of the grade to the second continue with the same teacher.

Other grade-progress schemes than those which merely alter promotion periods also have been tried—schemes that demand less uniform progress throughout any one year for children of different ability. The *Cambridge Plan*, which is probably no longer in use in any city of the United States, though a number of school systems have tried it, had a double-track system from grades four through nine, grade nine being a part of the elementary school. For the pupils who followed one track, the course of study was so organized that they would normally take six years to complete the elementary school program. For the brighter pupils who followed the other track, the curriculum was arranged so they could complete it in four years. The *Portland (Oregon) Plan*, discontinued there some years ago, divided the curriculum into six units per grade. The abler children were put into special classes which covered eight units in a year. Like the Cambridge Plan, the Portland Plan tried to accelerate the brighter pupils by allowing them to learn the course of study more rapidly, rather than by "skipping" them.

Neither of the above plans embodied a scheme for lessening the amount of nonpro-

motion that dull-normal and mentally retarded children would experience. Besides having special classes for the mentally retarded, which are provided in some school systems, schools try to keep the slow learner from repeating a grade by giving him extra help through special individual instruction and remedial teaching. Under the *Batavia Plan* (*q.v.*) very large classes with two teachers to a class were organized, one of the teachers serving as a coach to the backward children.

In present practice, special tutoring for the slow child is an important part of the program for enabling him to maintain normal age-grade progress. He may get this special help at home; he may be kept after school by his regular classroom teacher; or he may receive special instruction during the day from a "remedial" teacher who serves the whole school. These tutoring schemes imply that with extra help and extra time devoted to study, the backward children can keep up with their classmates. If these pupils are backward because of absence, or because of some emotional maladjustment which kept them from learning as well as they could in a previous grade, or because they come from a foreign country and have not yet acquired sufficient command of the English language, extra tutoring may be beneficial. However, if their intelligence is low, their backwardness may be owing largely, if not entirely, to a slow rate of learning and to the fact that the material for the grade is too complex for their mental-age level. Extra tutoring plus perseverance on the part of the pupil can result in a marked increase in his verbal knowledge of facts. Therefore, in so far as the school promotes on such a criterion, these specially coached children of low intelligence will be promoted. For such children, however, promotion means an increasing rather than a decreasing struggle in the next grade.

That educators confuse children's readiness for starting upon a group of specific learning tasks (which corresponds to entering a specific grade) with the pupils' ability to keep pace with other children who start out with them is evident in most promotional schemes. It is seen clearly in practices with regard to promotion into and from the first grade. For many years educators have been disturbed by the number of children who fail in the first grade and are not promoted. The proportion

PROMOTION

of first-grade repeaters has been estimated to be twice as high as the proportion in any other grade. On the assumption that children below the mental age of six are not ready to begin the work of the first grade, some schools keep such children longer in the kindergarten or provide a prefirst or junior first grade. Once they have entered the regular first grade, however, they are expected to keep pace with the other children. This substitute for nonpromotion has the advantage that it may eliminate the feeling of failure and thus remove one of the factors that bring about antagonism toward the school—antagonism that may in turn result in poor school work. Such prefirst grades are of greater advantage to the child of poor background than to the child of low intelligence. They provide the school with an opportunity to give the child experiences which he did not get in his pre-school years, experiences particularly necessary for a successful grasp of verbal material. Although the child reaches the second grade at the same time that he would have if he had been allowed to enter the first grade and then been made to repeat it, there has been no grade repetition. The pupil has not had to go through the same curriculum twice. If the succeeding grades continue to enrich these children's lives sufficiently to make up for their continuing poor home environment, then they may continue to keep pace with other children whose home life provides them with comparatively rich experiences. Otherwise the same factors that kept them in a pre-first grade will bring about periodic nonpromotion in later years.

A different attack on the problem of first-grade failure has come from those who concluded that a large proportion of this failure was owing to the fact that the curve of learning at these younger ages is very uneven and is different for different children. It was observed that some children make a slow start in learning to read (often the sole promotion criterion in the primary grades), but later progress rapidly; while others maintain a steady pace and still others learn rapidly at the start and then slow down. Some school systems, therefore, do not put the children to a test until the end of the third grade, nonpromotion in the first two grades being eliminated completely.

Recognition that the curve of learning is

different for different children (even of the same intelligence) and different for the same child in different subjects has led some school administrators, still a small minority, to institute schemes which do not demand that all children in the class reach a specified goal before they can continue to the next grade, while those pupils who reach the goal before the specified promotion date are compelled to mark time in the meanwhile. The shift from lock-step group progress to individual progress necessitates a simultaneous shift from group teaching to more individualized instruction. (See INDIVIDUALIZED INSTRUCTION.) As soon as the attempt was abandoned to fit every pupil's progress to the grade divisions of the school, and instead instruction tried to adjust itself to the varying learning needs of pupils housed together in one classroom, it was possible for the bases for promotion to be changed. The problem of promotion now became the problem of placing each child in a group in which he could do his best learning and make his best adjustment emotionally and socially. Social maturity became as important a promotion criterion as present scholastic achievement. Some schools announced a one-hundred-percent promotion policy which allowed children to move along with their own age groups, except in those cases where it was considered advantageous to their own adjustment to have them transferred to another group.

The objection was raised, of course, that this meant all meaning was removed from the concept of a school grade. To this objection was countered the argument that grades had never had any more uniform meaning than a certain number of years of attendance in school. The results of standardized tests applied to schools in various parts of the country showed that no grades anywhere consisted of pupils who had attained the same standard of achievement and that the average achievement of the same grade differed widely from school to school. A truer description of a child's achievement would therefore be the scores he obtained on standardized tests.

The elimination of the policy of nonpromotion is still rare, however, except in progressive private schools, and very few dull children enter these schools. While many public schools are making a serious attempt to reduce the incidence of nonpromotion, they are

not willing to abandon the policy of non-promotion. Moreover, it is doubtful whether the abandonment of nonpromotion is helpful unless there is a reduction in class size and unless there are changes, too, in the curriculum and in methods of teaching.

Although the problem of nonpromotion is usually discussed in terms of the elementary school, it is just as serious a problem in the high school. In all but a small percentage of American high schools promotion is by subject rather than by grade. A student may fail one or more courses, and he repeats only those courses in which he has failed. In some high schools the incidence of course failure is alarmingly high. Children who never experienced failure in the elementary grades fail courses in high school. One study found that about a third of failing high school pupils had been promoted regularly from grade to grade in the elementary school. Others found that the majority of failing high school students are of average or better intelligence. While the trend in the elementary school is toward practices which reduce the amount of failure, the secondary school has not yet been as determined in the attempt to reduce retardation. Students are known to have repeated the same course four times. There is an especially large proportion of failures in foreign language and mathematics courses. English courses also are failed by many pupils. This high degree of the incidence of pupil retardation in secondary schools has been attributed to such factors as poor methods of teaching, curricular offerings of little interest to present-day youth, and to failure on the part of high school administrators to realize that compulsory education laws are bringing to the high schools large numbers of students of average and below-average intelligence whose needs and interests are markedly differently from those students of the college preparatory group for whom the secondary school so often reserves its major concern. (See CLASSIFICATION OF STUDENTS; ELIMINATION, SECONDARY EDUCATION.)

PROTESTANT EDUCATION. A picture of Protestant education can be seen in three basic institutions—the local church, the home, and the college.

The Local Church. In the local church the Sunday school is the major educational agency. Founded by Robert Raikes in 1780, the Sunday school has become a widely extended agency of religious education for Protestant churches. It covers one session, usually an hour, on Sunday morning or afternoon. The program consists of worship, presentation of missionary and service projects, and a period of a half hour for the study of the lesson for the day in classes running from a dozen in most cases up to the large adult Bible class of several hundreds. The lessons emphasize the study of the Bible and its practical meaning for life. No single set of lessons is used in all schools, although the Improved Uniform Lessons selected by a committee of denominational editors of the International Council of Religious Education is the one series of lessons most widely used. Other lessons are built upon the principle of close gradation by years, usually known as the Closely Graded Lessons, or upon the broader plan of grading which covers a three-year span. These are known as Departmental or Group-Graded lessons. Many elective courses are used. (At the time of preparing this statement a comprehensive program for developing new outlines is under way. This program includes Uniform Lessons, Graded Lessons of several types, and outlines for the home, vacation church schools, weekday church schools, summer camps and small Sunday schools.) In addition to this Sunday session, the Sunday school reaches its members in other ways. Midweek or other meetings of classes for boys and girls and young people are held frequently. Many teachers secure a reasonable amount of home reading and study in connection with their lessons. The cooperation of parents is widely sought as a part of the teaching program itself and a good deal of such joint effort is secured.

Approximately 20,000,000 pupils are en-

rolled in the Sunday schools of the Protestant denominations of the United States and Canada. Upwards of 35,000,000 are enrolled throughout the world. Most of the teachers of these classes are not trained for their work except as they have been enlisted in the leadership education program of the various denominations and inter-church agencies. This teacher training program has been under way for many years and is an important factor in providing better leaders.

Next to the Sunday school, the young people's society is the most widely used type of religious education. There is no uniform name for such groups. They meet either on Sunday evenings or during the week. Organized by Dr. Francis E. Clarke in 1881, this type of work now includes in its membership, according to a recent estimate, about 3,500,000 members in the United States and Canada. In these groups young people conduct their own programs, with only a minimum of adult guidance or none at all. Worship, discussion of topics of both religious and social interest, service projects, and participation in the work of the church make up the program of these organizations. While some such groups are active in the Junior age—nine to twelve—and more reach the early and middle teens, the majority serve those above the high school age.

The Vacation Church School is one of the newer phases of the total program. Beginning about the turn of the century, in 1902, it has become an established part of the program. Sessions are held in the summer vacation for periods of two to six weeks during the forenoons of five days each week. Such schools make use of church buildings and the time of pupils and teachers which otherwise would be lost. The program includes many features of the Sunday school, although special stress is given to projects such as handwork, visitations and other activities. While adequate statistics are difficult to secure, it is estimated that about 30,000 such schools bring together over 2,000,000 pupils each summer. These are nearly all under fifteen years of age, with the larger number being under twelve.

Weekday religious education is another movement within the total field of Protestant education. It uses the weekday time of children during the regular school year, usually

in some relationship to the public school. In some cases classes are held in the churches of the denominations to which the children belong, with hours adjusted to the public school schedule. In other cases the pupils leave the school buildings to go to some building nearby where the Protestant churches cooperate in providing leadership. In still other cases, in harmony with local desires and conditions, classes are held in the school buildings. In any of these plans the work may be done either on a "released time" basis, with pupils excused from certain parts of the regular school program, or after the school program has been finished. This movement began in 1913 and now is estimated to be in operation in well over 500 communities, with an average attendance of about 400,000. These come from elementary and secondary school grades, with the former in the majority. (SEE RELIGION AND PUBLIC EDUCATION.)

The summer camp and conference for boys and girls and young people has been called the youngest and most rapidly growing agency in the family of religious education. The first of these was held slightly over twenty-five years ago. They are operated by national denominational boards, by the International Council of Religious Education, by state and city councils, and by local churches. Their purpose is to motivate and train carefully selected young people from the churches for carrying forward the ideals and work of the churches. There are now some hundreds of such enterprises in operation each summer, with several hundred thousand young people in attendance.

Adult education is conceived of as being carried out not only in Adult Sunday school classes, but through women's organizations, men's organizations and the church program as a whole, with increasing emphasis upon the educational use of preaching and public worship.

The parochial school, so widely used in Catholic churches, is not generally in use among Protestants. On the whole, Protestant churches depend upon the public schools for general education and the agencies discussed in this article for religious education. Some churches, particularly some Lutheran groups, have introduced parochial schools. There were 400 Lutheran elementary schools in

PROTESTANT EDUCATION

1840. In 1940 approximately 3,000 such schools were under the direction of the Synodical Conference of the Lutheran Church.

The Home. Protestant churches recognize that the most potent religious influence, either positively or negatively, is inevitably exerted by the home. They are just now discovering that much more could be done to make this influence of high educational value. A movement is under way to enlist religiously-minded parents as teachers of religion for their own children in a concerted effort such as has not been undertaken before. This effort will take two main directions: one, the use of the everyday experience of living in the home as opportunities for Christian character building and the development of Christian ideas, attitudes and practices; and the other, the use of special times for religious guidance through family worship, festival celebrations, and family discussions of everyday problems. Classes to train parents for this sort of teaching are being promoted, national emphasis is being given to the importance of family life, and materials to guide and help families in these ways are being prepared. While this movement is but in its infancy, many believe it is destined to be the most significant movement in Protestant religious education yet undertaken. It is intended not to supplant, but to enrich and reinforce the other agencies of religious education at work.

The College. The first schools in the New World were opened under church control. Influential in early primary education, the church also established secondary schools. From that point the churches began to establish colleges. The church in America has been a prolific mother of schools.

Before the Civil War there were 182 permanent colleges and universities founded. Of these about 146 were related to Protestant churches and 12 to the Roman Catholic Church. Many more were established between that time and the end of the century, but many had to close. However, many remain. Today of the 780 universities, colleges and junior colleges related to the churches in the United States, 553 are Protestant. Nearly half of the students in American colleges and universities attend church-related colleges. The church-related colleges have conserved the values of religion in education.

Credits in Bible, religion, and religious education are required for graduation in 82.2 per cent of these institutions; these colleges insist that the study of religion, as well as the practice of religion, has an important place in an educational program, since religion is necessary to enable one to face the problems of life. These colleges are active in preparing Christian leaders for all walks of life, including the schools, government, business, industry, and other vocations and professions, as well as for the ministry. In carrying out this broad purpose the churches also have extensive programs for their own young people attending state and other non-church universities.

Organizationally, the above activities are promoted and directed by national denominational boards of Christian education for the work in the church and in the home, and by boards or departments of higher education for the college level. The International Council of Religious Education represents the first of these and also works through state, city and county councils of religious education. The college boards work together through the Council of Church Boards of Education. PSYCHOANALYSIS—See PSYCHOLOGY, SCHOOLS OF.

PSYCHOANALYSIS IN SCHOOLS. Freud made few references to the educational implications of psychoanalysis, but the theories of progressive education and the principles of psychoanalysis are in accord. Pestalozzi, Froebel, and Dewey were concerned, as was Freud, with the psychological growth of children.

It was Freud's daughter, Anna, of Vienna and later of London, a teacher as well as an analyst, who began the direct application of psychoanalysis to children. Anna Freud and Melanie Klein of Berlin, later of London, did extensive therapeutic work with young children. They gave lectures and seminars for lay and professional groups at the institutes and child centers. Many American universities provide mental health service to students by psychoanalytically oriented staffs.

Freudian terms are not applied to the modern methods of teaching but many of the principles implicit in psychoanalysis are accepted in modern education. More often the terms are strenuously resisted by teachers though the principles are accepted and reworded. Thus, teachers and educators speak of a child's need to find an outlet for emotional expression and of the school's function to direct these impulses into creative channels; they do not use such terms as *id* or *sublimation*. Many educators realize that the teacher assumes the role of parent in the child's eyes and that because of specific child-parent relationship some students will react more favorably to women teachers and others to men teachers; but father or mother surrogate and transference are not the vocabulary they use to describe this. Other Freudian terms—repression Oedipus complex, unconscious—have filtered into the scientific and popular vocabulary.

Both analysts and educators are concerned with the problem of motivation. The popular use of mental tests in schools reveals that high I.Q. is not the single component of learning. The bright pupil often functions below his ability and has adjustment difficulties. The factor of emotional motivation and its effect on energizing, depressing, or

scattering the I.Q. have to be understood in the complete picture of achievement. Education has stressed conscious motivation, and the limitations of this partial analysis have led to an interest in Freud's basic principle of unconscious motivation as another facet in the learning problem. There is a consistency in the tendency of both modern educators and psychoanalysts to view the child as an organism; not to be divided into emotional and intellectual compartments. Both appreciate that the early years of life are formative of personality structure. The acceptance of this fact is indicated by the growth of the nursery school and by the use of psychologically trained social workers and other public agencies to cooperate with the home in aiding the young child. PSYCHOGRAPH—See PROFILE GRAPH.

PSYCHOLOGY OF SCHOOL SUBJECTS. The attempt to reduce the steps and factors involved in school learning to the basic processes, abilities, traits and environmental influences has produced a field of study known as the *psychology of school subjects*. The implications of research in the psychology of school subjects suggest changes in methods of teaching, in the curriculum, and in teacher education. Books on the psychology of school subjects deal with a large proportion of the problems discussed in books on educational psychology, the difference being that laws of learning and principles of evaluation are discussed directly in terms of their application to the various school subjects taken up in turn one after the other. It is natural, therefore, that as laws of learning are modified, revised and extended, that the psychology of school subjects becomes similarly changed. When educational psychology confined the principles of learning to Thorndike's famous laws of readiness, exercise, and effect, the major portion of books on the psychology of school subjects dealt with the application of these laws to arithmetic, reading, writing, history, etc. At present, the psychology of school subjects takes more and broader factors into account.

Subjects are discussed in terms of the motivation and maturation of the learner, in terms of the individual differences in these factors in children of the same age, and in terms of the meaningfulness of the subject-matter.

In many instances, specific learning experiments resulted in an immediate change in subject-matter teaching. When, for example, experiments disclosed that we perceive whole words as quickly as the separate letters making up these words, it was soon suggested that the child begin his study of reading by learning word forms instead of the alphabet. The contrast between a "psychological" and a "logical" approach was made still more specific by conclusions drawn from experimental studies of thinking, concept formation, and learning. The application of these conclusions led to such educational changes as the elimination of logical definitions of a peninsula, latitude, etc., from the introduction to geography, and the discarding from arithmetic textbooks of abstruse, unusual problems that have no counterpart in everyday life. As child psychology in turn became empirical, there was found in the facts and laws of mental development justification for further innovations such as the substitution of more natural writing movements for the earlier kind of training based on loops, whorls, and other formal elements of handwriting.

As the various school subjects themselves became the point of departure for studies of a psychological nature, the measurement of progress and of the attainment of the objectives in each field began to take on considerable importance. Techniques were devised for the construction of objective tests and scales in the various school subjects. This manner of presenting results quantitatively, along with the analytical viewpoint, led to a clearer differentiation of the skills needed within any field. For example, it was found that the instructional value of representative drawing is much less than that of schematic drawing in nature study, and that good oral reading is no guarantee that the child will show superior ability in understanding the sense of paragraphs. Techniques were also developed for determining the difficulty or maturity levels of elementary facts and skills requisite in arithmetic, algebra, geometry and other subjects. Empirical studies of errors commonly made by pupils furnished a con-

crete basis for the apportioning of drill periods, and when linked with the known facts of individual differences suggested modifications of approach to subject matter for bright and dull pupils.

Changing emphases in school aims have brought new problems with which the psychology of school subjects must concern itself. Emphasis on the need for understanding what is learned and on the ability to use known facts to solve new problems has, for example, resulted in a scrutiny of the verbal material presented to children and in suggestions as to how such material can be made more comprehensible. Emphasis on character development has led to an evaluation of teaching techniques not only in terms of the amount of subject-matter acquired but also in terms of the kind of personalities developed during the process. It is thus seen that though a fairly extensive collection of data already exists with respect to the psychology of reading, spelling, arithmetic, writing, drawing, science, literature, and language study, many changes may be expected as principles of learning and school aims are extended and clarified.

PSYCHOLOGY, SCHOOLS OF. While the term *Schule der Psychologie* (Schools of Psychology) was not uncommon in German psychological writings of the '80's in referring to a group of psychologists—usually centered in some one university—who differed from the orthodox teachings of Wilhelm Wundt, in the United States "schools" were of no significance and were rarely mentioned before the second decade of the present century. It is not that American psychologists were in major agreement with one another or with Wundt, or that psychology in this country had not yet fully matured for schisms. Rather, the main reason appears to

be that, with the exception of E. B. Titchener, most early American psychologists of note lacked the partisanship conducive to the founding of rigid schools or systems. William James, for instance, whose lone contribution to psychology is well on a par with that of a complete school, was often too tolerant and tentative, too broad and dynamic, in general too much of an individual, and in the end too critical and skeptical of psychology to uphold any set frame of its principles. John Dewey, whose 1896 paper on the "Reflex Arc in Psychology" is still a classic of psychological theory, early transcended the bounds of professional psychology; and G. Stanley Hall, the first president of the American Psychological Association, was also the president of Clark University, a position that did not remove him from psychology but was instrumental in making his writings, to use his own terminology, "synthetic" rather than systematic. James R. Angell, till recently president of Yale University, had indeed formulated the fundamentals of a system of functional psychology, but was too busy and too unconstricted to foster and champion it. Finally, at Columbia, J. McKeen Cattell and later E. L. Thorndike were developing—contrary to the doctrines of Wundt—a psychology of capacity and individual differences. But Cattell, Wundt's first assistant, unlike Wundt, was always wary of philosophizing and systematizing, and Thorndike, the youngest of the American pioneers, was too busy experimenting. Thorndike was, and still is, much interested in readily testable and verifiable specific theories, but apparently has little time or use for ubiquitous systems.

In the first years of the second decade, however, the scene of American systematic psychology began changing rapidly. Nearly all at once a variety of schools sprang up full-fledged and psychologists flew to the colors, taking sides and participating in heated controversies. Behaviorism usually traces its origin to Watson's paper, "Psychology as a Behaviorist Sees It," in 1913 and even farther back to his lectures before a seminar at Columbia University in 1912. Wertheimer's famous article on perception of movement and gestalt psychology came out in 1912, in German. McDougall's "Social Psychology" was published in 1908 and his "Psychology, the Science of Behavior" in 1912. Psy-

choanalysis was founded earlier, but was not really offered to American psychology as a possible school till Freud, at the invitation of Hall, had crossed the ocean to deliver a series of lectures at Clark University in 1909. Functional psychology, as already noted, had been existent for years, awaiting only advocacy and articulation, while all that the traditional structuralism of Titchener needed to arouse it from its official self-complacency, was a vocal opposition. The register of schools of psychology was thus filled in a very short time, and basically only few changes have occurred in it since.

The meaning and scope of a "school of psychology" may perhaps best be illustrated by a comparison with a school in philosophy and in art, two other disciplines in which schools play prominent roles. In philosophy a school is of course primarily a system of ideas, a more or less orderly arrangement of basic concepts and first principles. In art it is rather a system of skills and practices, a more or less consistent way of doing things. In psychology it is both. Schools of psychology and psychologists of various schools differ from one another both in ways of thinking (concepts and general principles) and ways of doing (special methods and techniques in the clinic and laboratory). The specific practices of psychologists often indeed have been the main immediate determinants of their theories, as witness the close relation between a certain method of studying animals and behaviorism, a specific technique of diagnosing neuroses and psychoanalysis, a process of investigating sensations and structuralism, a method of studying perception and gestalt psychology. But general principles also have had their effect, and one may attempt a connection between certain schools of psychology and certain schools of philosophy, as, for example, between behaviorism and materialism, functionalism and pragmatism. One may also argue that psychoanalysis is a middle-class revolt against social and religious taboos, while structuralism is an "ivory-tower" rationalization for detaching oneself from social issues. It is also possible in some cases to trace the rise of a school to the partisan personality of its founder and the loyalty of his followers.

Another recurrent question is why, of all sciences, it is psychology that is most split by

schools. The answer here must be sought not so much in the youth of the field as in its particular balance of facts and interpretations and its intermediate buffer position in the sciences. In mathematics, physics, or biology there are so many settled facts that basic differences in interpretations occur only in some generalized aspects—vitalism *versus* mechanism, corpuscular *versus* wave theory of light, Euclidean *versus* non-Euclidean geometry—which affect but little the diagnosis and solution of the average problems with which their scientists are confronted. In the social sciences, on the other hand, so many interpretations are possible that factual frameworks are hard to set, and their schools do not have the same systematic import nor are they so limited in number as in psychology. Systems of psychology could thus be expected to diminish as experimental evidence accumulates, a supposition that finds support in the reconciliation of some schools and in the diminishing importance of others. However, psychologists have also shown strong tendencies toward embarking upon new fields in which theoretical interplays are rampant; there has of late been some general fashion for conceptualization. In all, the future of psychology as a “science with schools” appears to depend upon the opposing factors of, first, how close it stays to an experimental laboratory science, and, second, how near it gets to a social life study. The chances are that psychology will hold on to both.

Structural Psychology (also **EXISTENTIAL PSYCHOLOGY** and **INTROSPECTIVE PSYCHOLOGY**). A school of psychology, most precisely formulated by E. B. Titchener (1867-1927) which traces its origin to the experiments and writings of William Wundt. In a large measure it was the “official” academic psychology of the last quarter of the nineteenth and the first decade of the present century. Titchener wrote in 1898 that “The subject matter of psychology is the morphology of the mind—what is there and in what Quantity, not what [it] is there for.” Mind is synonymous with conscious mind, and the only difference between mind and consciousness is that consciousness is “the sum-total of mental processes occurring *now*, at any given ‘present’ time” and mind is “the sum-total of mental processes occurring in the lifetime of an individual.” Titchener’s “quantity of

mind” does not signify an interest in capacity and group and individual differences, since structuralists consider the concern of psychology to be only the “generalized, adult, human, normal mind.” Quantity of mind merely means an introspective scaling of the degrees of intensity of the elements of consciousness. Titchener’s contention that psychology should not study “what the mind is for” intended to keep out “applied” and “functional” psychology and indeed any consideration of values. Another name for structural psychology is existential psychology, a name it derives from its endeavor to study consciousness, experiences, as facts or *existences* regardless of their function, use, or value. Science, according to Titchener, deals with facts and not with values. Values are non-scientific, or, better, extra-scientific. Because of the alleged nature of its subject matter, psychology even more than other sciences must guard against the intrusion of values.

The only method recognized by structural psychology is subjective observation or introspection, looking into one’s own internal experiences. This introspection, furthermore, must be specially “trained.” An untrained subjective observer is likely to lack scientific detachment, attend to the elaboration of his consciousness rather than to its immediate impression, study the external physical object or event rather than its internal psychological content (stimulus error). Trained introspection is not the “psychologizing” of a Dostoyevsky hero, nor the ratiocination of the philosopher or inventor, nor the musing of the artist or lover, nor even the common sense observation of the average man. It is a technical, exact, and specifically psychological method—acquired through long and vigorous training in the laboratory—which alone is capable of unraveling the real structure and laws of mind and consciousness. It may be used in *analysis* answering the question of “what” by reducing states of consciousness to their basic elements, and in *synthesis* answering the question of “how” by showing how these elements are combined and arranged. These basic elements—the elements of the mind discovered by trained introspection—are, according to Titchener (some structuralists do not agree completely), *sensations*, *images*, and *affections*. Images are “textually” different from sensations, being “more filmy,

more transparent, more vaporous," but like sensations they possess four main attributes: quality, intensity, duration, and clearness. Affections (the characteristic elements in emotion) lack the attribute of clearness. There are also special attributes such as extensity, volume, and insistence; and each attribute may further vary in kind and magnitude. All mental life is thus a kaleidoscope of the permutations, combinations, and fusions of elements, attributes, and their variations.

The early criticisms of structural psychology by William James, Henri Bergson, and Wilhelm Dilthey dented it but little. At present, however, its influence is no doubt small, even though because of inertia or the lack of other suitable material a good portion of it is still sedulously taught to our undergraduates. Current objections to structuralism are often not much different from those of old except that they are now more widely recognized. Consciousness, it is argued, is not a discrete content that is readily suspended and pegged, but a continuing operation that quickly effervesces; it is an activity leading to practical consequences rather than a sheer parallel state of experience (functionalists). Mental life is an organic whole that cannot be broken up into fortuitous component elements, and the elements of trained introspection are only laboratory artifacts (gestaltists). Of what value is a detached analysis of consciousness to the individual? Is not a psychology that leaves the individual and his problems out of consideration but a sterile diversion (clinical approach)? Introspection is unreliable and unfit as a method for a science, and behavior rather than consciousness should be the subject matter of psychology (behaviorists). Taken together, these criticisms reduce impressively the significance of Titchener's system. Historically, however, structural psychology did play a very significant role. It freed psychology from the paternity of philosophy and of purely armchair speculation. It created a consciousness of scientific methodology, of exact, technical, and unbiased observation, a mind-set which reached out to and pervaded the cognate fields of education and the social sciences.

Functional Psychology. A school of psychology which traces its beginning to William James, John Dewey, and James Angell, but finds considerable support in the works

of most early American psychologists such as Hall, Münsterberger, Baldwin, Ladd, and Cattell. It is also easily traceable to the influence of Charles Darwin. Functionalism is a rather open and loosely knit system, and a good number of contemporary unattached "middle-of-the-road," "reaction," and "dynamic" psychologists may well be gathered under its wing. It is also the most "American" of schools in origin, inspiration, and adherence. Its basic contention derives from the view that consciousness is adaptive in character, is an activity or function of the organism leading to practical consequences rather than being a mere structure. Psychology is therefore the study of the operation of mental processes, the conditions of their occurrence, and the utility or consequence of their functioning. Mental functions are psychophysical wholes involving an inseparable unity of the awareness of the act and the act itself. Psychology may even be considered the study of all the activities of the organism or the individual, inasmuch as they all become sometimes, if not always, psychophysical. Both introspection and objective observation are regarded as valid psychological methods, except that the former must not be a "trained" microscopic dissection and tail-chasing retrospection, but merely an accurate common sense observation, and objective observation must whenever possible be used as a check upon introspection. It is further recognized that complete experimental control of mental functions is often impossible and that other methods, particularly the study of social products—art, literature, language, invention, social and political institutions—may shed considerable light upon human mentality.

Functional psychology was clearly interested in studying mental life in its natural setting. In contrast to structuralism it deliberately concerned itself with values and with the application of psychology. Dewey's address in 1900, "Psychology and Social Practice," given as president of the American Psychological Association, was plainly a plea for, and a platform of, educational psychology. Applied psychology, industrial, social, and abnormal psychology, vocational guidance, tests and measurements—all sorts of problems in human growth, development, and learning—came in its wake or even preceded it. Indeed, there was hardly a problem of

practical human affairs which functional psychology did not claim as its rightful domain. It greatly expanded the scope of psychology, shifting more and more its emphasis from the subjective to the objective and from knowledge for its own sake to knowledge for use and control. It was little dismayed by the accusation that psychology was thus becoming more a technology than a "pure" science. On the other hand, functionalism was wary of radical changes, of elaborate deductive theories, and of cure-all broad generalizations, such as may be found in gestalt psychology, psychoanalysis, and behaviorism. It preferred slow, step-by-step, perhaps somewhat indiscriminate, cumulations of data, and limited, simple—one might say glamorless—conclusions.

In a large sense, functional psychology is still the most characteristic American psychology. Indeed, it was functionalism that first began to emphasize behavior and dynamics, two basic principles of all contemporary psychological systems, and called attention to motivation and goal-seeking, which are other fundamental concepts in current psychological thought.

Behaviorism. A school of psychology, associated primarily with the teachings of John B. Watson, which in many ways transcended the bounds of a psychological school to become a general philosophy. Behaviorism, like functionalism, is largely an American product, except that it borrowed its distinctive method and chief explanatory principle, the conditioned reflex, from Russian reflexology. The basic contention of behaviorists is that only objectively observable behavior from grossly motor to minute physiological reaction can be the subject matter of psychology and of any other human science, and that introspection is a futile or completely impossible and illusory method of observation. When an individual introspects he merely behaves in a certain fashion, and his behavior, mostly verbal, constitutes only a "verbal report." This verbal report is solely a set of responses; it does not stand for anything beyond itself, and does not reveal any unique mode of existence, or consciousness. Consciousness is thus denied existence, and the traditional categories of psychology—sensations, images, perceptions,

feelings, and the like—are held to have the same status as ghosts, souls, and animal spirits. This is the more radical view, the one proclaimed by Watson himself. Sometimes, however, consciousness is granted existence, but it is claimed that it is not subject to scientific investigation and that it is no causative, being a mere epiphenomenon, and that it therefore has no place in science, which deals with cause and effect. Mental categories, according to this argument, would be classed not under mythology but under literary rather than scientific psychology, to use Santayana's expression. At any rate, behaviorists agree that a science of psychology may be built only upon behavior and objective observation.

The skeleton of the behaviorist's system is rather simple. All behavior may be divided into three classes: motor, mostly manual; laryngeal or verbal, including both vocal and subvocal speech; and visceral. Most motor behavior is explicit, or readily observable, but a great deal of visceral and laryngeal behavior is implicit, not readily observable by the naked eye or ear or even by our present recording instruments. Behavior in which profound visceral changes predominate constitutes emotion, and the reverberations and modifications of these changes are at the base of all affective and esthetic activities. Thinking is a laryngeal subvocal habit—submanual in deaf-mutes—built up genetically through short-circuiting and gradual social suppression of early overt, or explicit, speech. The so-called unconscious is to Watson nothing more than the un verbalized reactions of our very early preverbal childhood as well as our implicit and unnamed visceral reactions, while memory is defined as a verbal reinstatement of habits. The conditioned reflex is the unit of habit formation, the agent through which the few congenital reflexes and native emotions (love, fear, and rage, according to Watson, though others dispute this list) of the infant are gradually transformed, by permutations, eliminations, and combinations, into the multitude of organized activities of the adult. The general aim of psychology is the prediction and control of behavior through the discovery of all the relationships between measurable stimuli and objectively observable responses, so that given a stimulus the response may be predicted, and

needing a response the appropriate stimulus may be found.

With the possible exception of psychoanalysis, behaviorism is the psychology that has had the widest popular appeal. Its appeal was indeed more than only popular, as witness the favorable attention which it has received from such sophisticated philosophers as Russell, Santayana, and Holt, and the interest shown in it by a good number of exact scientists other than psychologists. The reasons for this popularity were many. One might mention the simplicity of the system, its radicalism, its possible wide application to fields other than that of psychology, its seeming strict "scientificness," and above all the ambitious program of changing human nature which it set forth. The idea that man is essentially a machine may have been old and put forward many times, but the notion that this machine with all its complexities may be simply and scientifically studied and controlled in the laboratory as an aggregate of motor, visceral, and laryngeal gadgets, unhampered by the intrusion of such factors as difficult to control as mind and consciousness, was new and revolutionary. Particularly did this notion take hold because it was not merely a philosophical assertion but was seemingly backed by controlled methods and rigid experiments. Watson's famous assertion that given any healthy baby whatsoever, and his (Watson's) own specified world to bring it up in he could train it to become any type of specialist selected—"doctor, lawyer, artist, merchant-chief and, yes, even beggar-man and thief, regardless of his talents, penchants, tendencies, abilities, vocations, and race of his ancestors" was certainly a bold challenge to all that man knew of man. No wonder that a newspaper reviewer of *Behaviorism* hailed it as "perhaps . . . the most important book ever written. One stands for an instant blinded with a great hope."

But that was 1924. In 1943 few accord behaviorism such a lofty status, and one hears of its decline. It should be said, however, that in a way this decline is more apparent than real, that it is often more a loss of its individuality as a school than a lack of effect as a movement, and that the decline is but little due to actual experimental and logical disproof. Recent results on the effect of

maturational, the variability of human conditioning, and some philosophical weakness of behaviorism may well suggest modifications in the system, but have not shaken its foundations. The main reasons for the recession of behaviorism are probably the fact that it claimed too much, and that its complete success depends upon an extensive and untrammelled program of experimentation and a highly developed system of mechanical recordings. A complete control of the conditioning of infants and a total instrumental recording of man's behavior may be suitable material for a Huxley novel (*Brave New World*), but in actual practice is hardly feasible. The present status of behaviorism is not that of a school discredited by logic and the results of experimentation but is that of an unfulfilled hope destined to remain unfilled as long as mankind does not institute the conditions necessary for the wide functioning of its principles.

Conditioning. As a basic principle in behaviorism and also as a principle of learning which can be held apart from other hypotheses of the behavioristic school, *conditioning* deserves exposition on its own account. Since it has claimed to be the sole principle by which organisms are changed from what they are at birth to what they are in their maturity, it forms almost a school in itself. Conditioning is a form of learning or training which follows in essence the process described in the classical experiments on the salivation of dogs performed by the noted Russian physiologist and Nobel prize winner, I. P. Pavlov. In Pavlov's first experiments, the ringing of a bell came to elicit secretion of saliva in dogs, when the bell had been sounded a number of times before the animals were fed. Generalizing, it meant that a stimulus which was originally inadequate to bring about a certain response became adequate merely by being combined one or more times with the adequate stimulus of the response. The originally inadequate stimulus, the ringing of the bell, was named the *conditioned stimulus*; the adequate stimulus, the feeding of the dog, was called the *unconditioned stimulus*; the secretion of saliva in response to the actual feeding was termed the *unconditioned response*; and the secretion of saliva in response to the originally inadequate but later conditioned stimulus, the ring-

ing of the bell, came to be known as the *conditioned response*. Pavlov found that any stimulus that affects the animal in some way may become conditioned to the secretion of saliva. Other experimenters have since demonstrated that, besides salivation, nearly any other response may become similarly linked to a conditioned stimulus, thus establishing the universality of the phenomenon.

Conditioning is best effected when the conditioned stimulus either precedes by a few seconds or is applied at the same time with the unconditioned stimulus, for example, ringing the bell a little before or simultaneously with the feeding of the animals. Fair results also have been obtained when the conditioned stimulus is continued for a few minutes before the unconditioned stimulus begins to act, or even when the unconditioned stimulus begins shortly after the conditioned stimulus has stopped (feeding the dog after the bell has rung for a few minutes or shortly after the bell has ceased ringing). On the other hand, backward conditioning (ringing the bell after the dog stops eating) is extremely difficult, although not altogether impossible. As a rule, a conditioned response will diminish in magnitude and finally disappear, if the conditioned stimulus is presented repeatedly without the unconditioned stimulus (bell without food). This is known as *extinction*. An extinguished conditioned response regains some of its original strength after a lapse of time. This is called *spontaneous recovery*. A new stimulus, such as the flashing of a light, may acquire conditioning characteristics (e.g., ability to elicit salivation) by being combined with an already conditioned stimulus (ringing a bell). This is *conditioning of the second order*. Conditioned responses of the third, fourth, and even fifth order also have been claimed by some investigators. Conditioned responses are very generalized in their initial stage of training (the dog will secrete saliva also in response to other sounds), but in time, after considerable experimentation, the responses become very specific (e.g., the dogs are aroused by a bell of a particular timbre and intensity). Animals that have been subjected to strenuous training in conditioning, involving prolonged delays of feeding and subtle discrimination of tasks, may begin to exhibit functional disturbances or develop *experimental neuroses*.

As a general concept, conditioning is similar in many ways to the old doctrines of "association of ideas," the doctrine of Aristotle and of the eighteenth-century British associationists, and of nearly all nineteenth-century and early twentieth-century psychologists and educators. However, the specific differences between conditioning and association are equally striking. Conditioning does not deal with subjective ideas and images but with objectively and accurately measurable stimuli and responses. It has established a good number of clear-cut quantitative generalizations and has supplied a variety of testable hypotheses for psychological and social and even some biological problems. Pavlov's findings on dogs have in the main been confirmed by experiments on infants a few days old and on one-celled animals, while general principles of conditioning have been claimed by careful investigators to be operative in such diverse acts as memorizing stanzas of poetry and acquiring immunity to a disease, acquiring racial prejudices and learning a foreign language, learning to typewrite and fearing darkness, liking some particular music and forming some specific phobia.

The number of systematic contemporary texts that use conditioning as the chief explanatory concept is considerable. One might mention Allport's *Social Psychology*, Burnham's *The Normal Mind*, Guthrie's *The Psychology of Human Conflict*, Sandiford's *Educational Psychology*, Shaffer's *The Psychology of Adjustment*, and Watson's *Behaviorism*, and *Psychological Care of Infant and Child*.

The chief difficulty in accepting conditioning as the universal principle of human modifiability is the extreme lability of the conditioning of adult human subjects under normal laboratory setups. In the past forty years about fifteen hundred separate experiments on conditioning have been performed, but clear-cut and consistent results have been obtained only with animals and, to some extent, with young children. Adult human conditioning has not, as a rule, met with great success, since it requires special setups and very special and limited responses and techniques, and even then yields heterogeneous and, at times, fragmentary data. The hopes of early behaviorists that conditioning would supplant verbal methods in testing human capacity and

effecting human modifiability have certainly not materialized. On the contrary, man's verbal equipment—and whatever else there may be to "mind"—seems to dominate the conditioning of his bodily activities. Attitudes, mental sets, interests, and situational arrangements appear to determine human conditioning more than do mere quantitative stimuli relationships. This does not mean that conditioning is insignificant genetically in shaping personality, nor that it is unimportant in a vast number of adult life situations, and not even that our verbal equipment itself may not ultimately proceed in accordance with some laws of conditioning. All it intends to stress is that, so far, all the complexities of human nature and conduct cannot be gauged adequately nor controlled by the known facts and techniques of conditioning, and that in our present state of knowledge other methods are often more appropriate.

Gestalt Psychology. A school of psychology founded by the German psychologists Max Wertheimer (1880-), Kurt Koffka (1886-1941), and Wolfgang Kohler (1887-) which has influenced considerably all contemporary psychological thought. The term *gestalt* usually has been translated into English as *configuration*—sometimes also pattern, form, shape, whole phenomenon—but of late the German word has been more prevalent both as adjective and noun. The basic tenet of gestalt psychology is that all mental life—and for that matter all existence—consists of segregated organized wholes, or *Gestalten*, possessing their own unitary structure and governed by their own intrinsic laws. The structure of *Gestalten* is such that they may not be analyzed or decomposed into component parts or elements—sensations, elementary feelings, relations, reflex arcs. *Gestalten*, or wholes, are not only more than the sums of their parts, but it is the wholes, or *Gestalten*, which are in all respects—psychologically, logically, and chronologically—primary to the parts and determine the parts rather than vice versa. Some of the laws of *Gestalten* are said to be (1) *transposability*, the complete carry-over of a gestalt from one situation to another, such as the equivalence of a melody in different keys; (2) *closure*, the tendency of a gestalt, if incomplete, to complete itself, as in the alleged greater persistence of an interrupted task or impression;

(3) *Prägnanz*, the tendency of a gestalt to assume its best form to become more typically what it is; and (4) *Figure and Ground* as illustrated by the sharpening of an experience after a lapse of time, and the separation of a gestalt into a more definite and less definite aspect, as exemplified in most perception—the perception of a tune and its accompaniment, for instance.

The initial work and thought of gestalt psychology was in the field of perception, but in time it extended to learning and memory, growth and development, thinking and feeling, and even intelligence and personality. In learning and memory, gestalt psychologists argue against the use of meaningless "unstructured" tasks, the concept of trial-and-error, the laws of use, disuse, and effect, and connectionism in general, while they emphasize insight, perceptual factors, total organization and understanding. Learning is said to be more perceiving and patterning than doing and drilling. Retention and forgetting are not just "stamping in" and "stamping out" of disparate movements and sounds, but meaningful "structured" reorganization of total phenomena and fields. In growth and development, gestalt psychology leans heavily toward heredity and maturation as against environment and learning, and also stresses orderly individuation, or the organized emergence of individual reactions from a total organismic background *versus* integration as a mere combining and chaining of reflexes and acts. In intelligence and personality, qualitative approaches are favored and unique central characteristics rather than sums of scores and traits are upheld. In all, the fundamental concepts of the gestalt and its laws are never lost sight of and always put forth freely as explanatory principles of all mental life.

Gestalt psychology has been criticized for the vagueness of its concepts and the extreme generality of its stated laws. To be sure, its generalizations are at best only qualitative and perhaps of little specific predictive value. Still, adherents of gestalt psychology point out that some of its basic hypotheses, even in such fields as neural organization and biological development, have been partly confirmed by some of the best and most exact experimentation (Lashley, Coghill, Weiss), and that in concrete human situations pure quantita-

tive laws are of little aid and often no more than mere abstractions. Sometimes it has also been said that gestalt psychology takes mental life out of the realm of science, since science can deal only with repeated events, and gestalt psychology insists upon the uniqueness of mental phenomena. The answer here would be that the point is not what mental life should be in order to conform to the framework of other sciences, but what it actually is. If it cannot be accommodated to existing scientific methodologies, it must seek and build a methodology of its own. Finally, it is frequently claimed that gestalt psychology suffers from an overemphasis of one aspect of experience—in itself as old as Anaxagoras and Aristotle—and a neglect of others, that it has magnified and inflated this one aspect by continuous repetition into a whole philosophy and world-view. In view of the fact that gestalt psychologists base their theories chiefly upon studies from their own institutes and laboratories, and are little familiar with or neglect the vast research of American laboratories, which often fail to confirm gestalt results, this criticism has a particular cogency. In all, it seems fair to state that, while gestalt psychology brought in fresh orientations and new positive knowledge, its chief contributions to psychology may still be said to be that of unmasking the shortcomings of other psychologies and of “unsolving” a number of problems that were thought to have been solved. It has shown that even the simplest psychological tasks are not so simple as the simplifying psychologists thought them to be.

Psychoanalysis. As a school of psychology, psychoanalysis occupies a unique position, differing distinctly from all other major psychological schools. The schools we have considered are all academic, born in the university laboratory, and fostered by experiments, tests, and statistics. But psychoanalysis was for a long time kept out of academic halls, and even now its recognition is often unofficial. Its cradle was the clinic, its subject matter the mentally sick and distorted. Psychoanalysis seems to care little, if at all, for traditional testing and experimenting. It claims its own methodology and its own criterion of determining evidence. It argues that all other psychologies are, by comparison with it, abstract, impersonal, and intellectualistic, and deal only with fragmentary, delu-

sive, and by themselves unrelated surface phenomena; while psychoanalysis is a “depth psychology” delving beneath and beyond, into the real roots and springs of human action. It is the true psychology of feelings and desires and the only one which unveils the psychic or mental causes of all our activities. The methodology of psychoanalysis as a study of the individual is hard to class with other psychological methods. It certainly is not introspection, or subjective observation of consciousness, not only because consciousness is, according to psychoanalysis, only a very small section of the mind, but also because typically the psychoanalyst observes others rather than himself. On the other hand, it is difficult to regard this methodology as objective observation both because “objective” implies a checking of results obtained by different observers and by the same observer at different times, and because the analysts so often supplement their direct observation by a large amount of inference. It has been said that psychoanalysis uses an essentially rational method to probe the irrational nature of man. In some way, psychoanalytic methodology is related to that of German *Verstehungs-psychologie* (understanding psychology) in which the understanding of an event is said to involve all the powers of the mind, the rational and the appreciative, and to transcend the mere strict logic of scientific evidence. At any rate, the methodology of psychoanalysis has been its main barrier in academic circles and the chief source for its criticism.

In a broad systematic sense, the chief tenet of psychoanalysis is the doctrine of unconscious psychic motivation, but Freud himself laid down three minimum fundamentals: the unconscious mind, repression and resistance, infantile sexuality and the Oedipus complex. By the unconscious mind is meant the existence within the individual of mental or psychic processes—ideas, wishes, strivings—which are neither in the individual’s immediate awareness nor may be normally recalled at will, but which constitute the largest portion of his mind and the motivating source of his action. Besides the unconscious there are a foreconscious, or preconscious, mind of readily recallable psychic processes, and a conscious mind of immediate awareness. Since 1923 there was also postulated by Freud

a topographical division of personality into the *Id*, the reservoir of unconscious instinctual impulses and passions; the *Ego*, a transformation of part of the *Id* by external reality, and a storehouse of perception which is, however, partly unconscious; and a *Super-Ego*, an inhibiting parental and social modification of the *Ego* corresponding to the popular "conscience". The theory of repression maintains that the unconscious mind is formed largely (part of it is innate) from conscious desires repressed by the conscious *Ego* while the doctrine of resistance holds that the unconscious part of the *Ego* resists the return into consciousness of the repressed desires. "Sexuality"—or *Libido*—in psychoanalysis is a broad term which covers everything that colloquially is called "love" or "affection," but since this love or affection presumably possesses the same characteristics as physical sexuality, the concept assumes a unique psychosexual connotation. Infantile sexuality denotes that this psychosexuality manifests itself right after birth—and even before—and its course largely shapes the future personality of the individual, while Oedipus complex is the direction of this infantile sexuality toward the parent of the opposite sex, or some parent substitute. Two other cardinal concepts are *conflict* and *polarity*, and further significant formulations are the *death instinct*, *ambivalence*, *regression*, *transference*, *conversion*, *dream analysis*, and a variety of others.

Psychoanalysis doubtless has been criticized more than any other school of psychology; nevertheless it is by no means on the wane and apparently continues to penetrate new fields and to gain new adherents, sometimes even among those who originally disdained it. The criticisms of psychoanalysis are directed primarily against the validity of its evidence; its unscientific methodology; its loose, sometimes inconsistent, delineation of concepts; and its highly figurative, personified, and reified terminology. One academic psychologist calls the process psychoanalogy. The rebuttal of the psychoanalysts is that mental life need not conform its method to those of the physical sciences, that it may have its special criteria of what constitutes proof and truth, and that their system is advisedly loose and open, to be modified by

further practice and discovery. To be sure, specific psychoanalytic hypotheses may be put to experimental and statistical verification, and some of them have actually undergone this test. But just as gestalt psychologists argue that an introspective analysis of a bit of experience may destroy its very nature, the psychoanalysts hold that conventional experimental and statistical setups may upset the essence of their methodology and the technique of their discovery. At any rate, even if most psychoanalytic assumptions should prove false and unworkable, their direct influence upon psychology has been tremendous and can hardly be exaggerated. Psychoanalysis has stimulated studies in motivation and personality, two of the most popular topics of contemporary psychology, which before had been practically neglected. It has helped in opening up to psychology the rich fields of psychopathology and mental hygiene, with its ramifications into functional genesis, psychological prophylaxis, and verbal therapies. Finally, it has brought forward to psychology the clinical approach, the problem of dealing with concrete individuals, with single cases—calling attention to the limitation of a psychology which is only, to use Gordon Allport's term, actuarial in prediction and practice. In all, it has brought psychology closer to life.

Purposive or Hormic Psychology. The psychology of William McDougall (1871-1928) which holds purpose, goal-seeking, and active striving to be fundamental categories of behavior and consciousness, and stresses the role of instincts in human life. The doctrine of instincts has since fallen into disrepute, but at one time (1906-16) it held sway over all social sciences. On the other hand, goal-seeking has become an increasingly lively concept which has found a place for itself in almost every major psychological trend. Even some behaviorists of the present day have reformulated the principles of that system sufficiently to include the concept of goal-seeking.

Purposive Behaviorism. The psychology of E. C. Tolman, which attempts a synthesis of behaviorism, gestalt psychology, and purposive psychology. Tolman emphasizes the need of postulating intervening variables between stimulus and response and considers

goal-seeking to be an objectively observable aspect of behavior.

Topological Psychology. The psychology of Kurt Lewin (1890-), which on the one hand is an extension of gestalt psychology into the fields of action, will, temperament, and personality, and on the other hand uses mathematical topology, the science of nonmetric space, as a tool of research.

Personalistic Psychology. The psychology of William Stern (1871-1939), which regards the total human personality as the only unit of psychology, as opposed to the division of personality into elements and traits. Stern was much interested in educational psychology and the psychology of childhood.

Individual Psychology. The teachings of Alfred Adler, who in 1911 broke away from the psychoanalysis of Freud. Instead of infantile sexuality, Adler stresses feelings of inferiority and goals of superiority (masculine protest, striving for prestige) as the chief motivating forces of life. He lays less emphasis upon the unconscious and more upon purpose, compensation, and the permanent "style of life" which the individual adopts in early childhood.

Analytic Psychology. The psychological system of Carl Jung, who dissented from the teachings of Freud. Jung stresses the collective or racial unconscious much more than does Freud, and does not give to childhood experience the significance attached to it by both Freud and Adler. The concept of the libido is to Jung a general urge toward growth, activity, nutrition, and reproduction. The concept of sex is a less pervasive principle than does Adler. Jung gives it more importance than does Adler. Jung is the founder of the typological concept of *introversion* and *extroversion* (q.v.).

Marxian or Dialectical Psychology. Contemporary psychology in the USSR, based upon the teachings of dialectical materialism by Marx and Lenin. Dialectical psychology is similar to functional psychology in its view that consciousness is adaptive in character, to behaviorism in its extreme environmentalism, to gestalt psychology in its consideration of total organization and qualitative factors, and has the distinctive features of regarding economic factors as primary determinants of hu-

man nature and of using dialectics as general working hypotheses.

Reflexology. A Russian variety of behaviorism with a much greater interest in the study of neural foundations of behavior. Historically reflexology preceded behaviorism but was much more naive in its psychological systemization.

PSYCHONEUROSES—See NEUROSES.

PSYCHOPATHIC CHILDREN. Psychopathic children are characterized mainly by emotional impulsiveness, lack of discipline, marked amoral and antisocial behavior, sudden moods, and an inability to modify or inhibit incorrigibility despite punishment and educative experiences. These children present serious problems of delinquency and social maladjustment, but they constitute only a small proportion of the emotionally disturbed children. (See MENTAL HYGIENE.)

PSYCHOSIS. Psychosis is a severe mental abnormality in which the individual is unable to adapt socially, professionally and intellectually. He is a liability to himself and society and is adjudged to be insane. Psychologically it is the disharmonious working out of the normal conflicts of the mind. This

PSYCHOTHERAPY

conflict is resolved in the normal personality by a harmonious balance of the various psychological forces by successful repression or sublimation of some fundamental drives. In the psychotic personality the inadequately repressed urges activate behavior incompatible with reality. The modern point of view concerning the region of psychosis is known as the *organismic* or *psychosomatic* point of view, which regards all mental diseases as having both physical and psychical causal factors. In some cases, however, the organic or physical cause is of primary importance and we refer to an *organic psychosis*. When, on the other hand, the causal factor of primary importance is psychic, we refer to a *functional psychosis*. Functional psychoses are the most frequent of the mental disorders. Their principal forms are the schizophrenias and the manic-depressive psychoses. Close to 45 per cent of the resident population in hospitals are schizophrenic.

Schizophrenia is a disease which breaks out in its acute form in the adolescent period or later. Its symptoms are much introspection, daydreaming, little contact with reality, difference and frequently mental reduction. There are many psychological theories of the causative factors of schizophrenia.

The *manic-depressive* is the second most frequently admitted of the psychoses. About 12 per cent of the new admissions to the mental hospitals are so diagnosed. Seventy-five per cent of these are females. Manic depressives are characterized by moods alternating between depression and elation. The elated manic state is marked by flight of ideas, lack of inhibitions, egocentricity, excitement and anti-social acts committed without guilt or remorse. The degrees of mania may range from excessive restlessness, impatience, and fast incoherent speech to violence, destructiveness or delirium. The precipitating factor, which is a catalyst already determined in the underlying dynamics of personality, is usually the loss of love object or an extreme frustration. The loss may be of a friend or of money or position. The frustration may be failure to get ahead, to gain a desired position, or arrive at some type of goal. All people are depressed at similar losses. The original depression may be looked on as simply an exaggeration of normal reaction to loss and frustration, but the degree of depression is extreme in the psychosis. It is characterized

by feelings of dejection, hopelessness, inactivity, withdrawal from people, and self-accusatory delusions. Severe irrational guilt feelings occur.

Psychoses of any sort are extremely rare in children. Accurate figures as to the precise incidence are not available because of the variability of diagnostic standards from clinic to clinic. The appearance of schizophrenia in early childhood is the most frequently observed and is higher in boys than in girls. Other psychoses of the manic-depressed juvenile parietic and epileptic type have been reported, but they appear rarely and often are not true psychoses. Hyperactivity is common in normal children and is difficult to diagnose as different from manic reactions. (See MENTAL HYGIENE.) J.F.B.-2

PSYCHOTHERAPY. Psychotherapy refers to that phase of the treatment of psychic disturbances which uses psychological methods to influence the patient's readjustment. The goal of treatment is to help solve the emotional conflicts giving rise to the problems, to effect an adjustment of the individual to the reality situations with which he is confronted and which he will have to face throughout life—in total, to bring about a better integration of the personality. Manipulation of the environment may be utilized as a help (social therapy), and other types of treatment may be employed also, but where there is a disturbance of any severity, it is essential that adequate provision be made for psychotherapy or the treatment of the patient to effect emotional and attitude changes, desensitization to adverse environmental attitudes or help in handling them to make reality situations more tolerable.

In all psychotherapeutic procedures, the relationship established between the patient and the therapist is of major importance. As soon as the patient is accepted for treatment he is made aware that the psychiatrist looks upon his problems and difficulties as significant

and worthy of his full consideration and attention. Fundamental to the establishment of the therapeutic relationship is a friendly, nonjudgmental, tolerant, acceptant attitude on the part of the psychiatrist. Through this the patient is able to relate himself and unburden his problems, without fear of condemnation or criticism.

Treatment cannot be symptomatic; that is, it cannot be directed solely at the removal of the symptoms the patient presents. It must be directed at the underlying conflicts, the release of the emotion attached to them, and the re-education of the individual so that he is able to function adequately and with reasonable efficiency. The forms of psychotherapy may be divided into superficial and depth therapies.

The superficial therapies consist of reassurance, suggestion, persuasion, and reconditioning. The first three are self-explanatory. Reconditioning consists of bringing the patient into contact with the thing feared, simultaneously with the introduction of a pleasant stimulus. These forms of therapy are not too successful because the phobia, fear, or anxiety may be displaced elsewhere and reappear subsequently as another type of symptom, such as withdrawal from social contacts, inability to work adequately, etc. In general, while the more superficial forms of therapy may be of some value in less severe psychic disturbances, their value is usually only temporary, inasmuch as the underlying conflicts, with their accompanying emotional components, in many cases, have not been uncovered or resolved. They may be useful adjuncts, however, to the techniques of depth therapy, which include psychoanalysis and other forms of analytical and resynthesizing techniques.

Depth therapy aims at the uncovering of the stress producing conflicts. In psychoanalysis, a specific technique in psychotherapy, the psychoanalyst helps the patient analyze himself and become aware of the nature of his problems through free verbalization on the part of the patient, interpretation by the analyst as he sees the need, and development of a rapport between the patient and psychiatrist which allows the patient to bring to the surface and release the emotion attached to the painful areas, i.e., the bringing of unconscious conflicts to consciousness.

In any form of analytical therapy the patient can expose in himself the material, emotional as well as factual, through which the patient and therapist will work to achieve a satisfactory adjustment.

All psychotherapy rests upon the foundation that the patient wants to be helped or is willing to be helped. The treatment relationship is not always a "friendly" one. At times, the attitude toward the psychiatrist may be decidedly hostile and resistive. As treatment progresses and the patient becomes resistant to opening up emotional areas which, of necessity, are painful and distressing, he may try to withdraw from treatment. The relationship which develops between the psychiatrist and patient reveals predominating trends in the patient's personality and brings out the tendency which exists in everyone to relive childhood emotional attitudes toward persons in their present environment (transference). Treatment is usually of fairly long duration and requires frequent, regular contacts with the psychiatrist. The results are not seen too quickly in most cases. The emotional disturbances which have been built up over a period of years require treatment which may extend from several months to several years. There is also involved in successful treatment the understanding and cooperation of the people in the patient's environment.

The treatment of children's difficulties usually involves both parents and child. Therapy is directed at the parents to effect changes in attitudes toward the child and to help parents achieve an understanding of their own motivations and the release of their anxiety. The child usually is approached best through the medium of play therapy, of which there are many varying techniques. Essentially, play therapy is a means of dramatizing and releasing emotional tensions through the use of dolls and other toys, upon whom are projected the problem-producing conflicts. Of equal importance here, as in the treatment of adults, is the relationship existing between the child and therapist which permits the child to experience his conflicts in relation to a person who can understand them and help him to do so. Equally significant is the help given him to carry over into his everyday existence the more comfortable attitudes he has developed in the treatment situation.

Essentially, there are four phases to any effective psychotherapeutic procedure: (1) establishment of good relationship, (2) release of anxiety or resolution of the conflict, (3) insight into and recognition of the problem, and (4) reintegration of the personality. (See MENTAL HYGIENE.) G.M.A.

PUBLIC EDUCATION, COST OF — See FINANCE, SCHOOL.

PUBLIC OPINION AND THE SCHOOLS — See PUBLIC RELATIONS, SCHOOL.

PUBLIC RELATIONS, SCHOOL. The school's "public relations" generally refers to its organized information service for the purpose of keeping the public informed of its educational program. In this narrow sense, "public relations," differs little, if at all, from the term "publicity" and implies that all of the contacts between the school and the public are planned with a definite purpose of informing the public. That such is the case is far from the truth. There are innumerable contacts between the school and public that are not a part of any definite plan for informing the public of the educational program of the school but which may be even more effective than are the planned contacts in creating either favorable or unfavorable impressions. The impressions that the public receives as a result of any contact, planned or unplanned, constitutes what is known as public opinion. Therefore, it is essential that all contacts, no matter how unimportant or insignificant they may seem, should be of such a nature as to result in favorable impressions.

Public opinion, from the early days of our republic to the present, has exerted a strong influence upon public education. The control of public education, vested as it is in the

people of the state and in local representative groups, has insured the public against the possibility of having an educational system of which its citizens do not approve.

In spite of the fact that the majority of the public has a generally favorable point of view toward public education, believing that education has been improved and rejecting the idea that it has been overemphasized, there exists in many communities a lack of understanding between the professional educators and the lay public. Citizens who have opposed changes in the educational system have appeared to the educators to be obstructionists, if not actual enemies of education, while the educators have appeared to the citizens to be idealists, opportunists and tyrants.

Such lack of understanding is regrettable, and although it is more likely than not to occur in any community at times, it can be lessened, if not prevented, through a well-planned program directed to this purpose. It must be remembered that the public has less chance of being well informed regarding educational objectives, practices and needs today than in earlier times, when education was less extensive and complex and when both the schools and the communities they served were smaller.

There is no evidence to suggest that more than a few citizens of today are less interested than were their forefathers in providing the best educational program they can afford. However, the increasing total amount of money paid in taxes each year has led most citizens to become more critical of any changes in the educational program that are likely to increase school taxes.

Taxpayers cannot be expected to be willing to finance any project which they are not convinced is worthwhile or necessary. Since the public looks to the education profession for leadership in matters pertaining to public education, it is the responsibility of educators to collect, organize, and present to the public all the facts necessary for an adequate interpretation of the educational needs of society and to take the leadership in arriving at proposals for meeting these needs. Unless this is done, there is much evidence which suggests that organized groups backed by large taxpayers who are more interested in reducing school taxes than in meeting the educa-

tional needs of society will be increasingly influential in guiding public opinion.

In the past, many educators have confined their efforts in public relations to those situations in which it has been expedient to inaugurate a publicity campaign of one kind or another to convince the public of the need for some suggested change in the school's program in order to gain the necessary approval or financial support.

Today, more and more educators are coming to recognize the need for a continuous program of interpreting the school to the public. They are accepting the responsibility of keeping the public informed of (1) the reasons for the school's existence, (2) the extent and nature of the educational program, (3) the needs for improvement, and (4) the need for changes to meet new conditions in society. In order that everyone in the immediate community may be informed, every available facility for transmitting the information to the public is used, including public newspapers, school publications, teacher-relations, pupil-relations, exhibits and demonstrations, public addresses, parent-teacher organizations, mothers' clubs, the radio, the church, and other public community agencies.

When such arrangements are practicable, the facilities of the school are made available for the use of the public. Teachers and pupils as well as school administrators are taking an increasingly active interest in community affairs. Everything is done to make apparent the school's contribution to the welfare of the community, while at the same time the school attempts to make use of the resources of the community, thereby bringing more and more people into direct contact with the school and its educational program.

The public relations program is dignified, yet positive and aggressive. All facts, good and bad are presented in clear, concise and understandable language. No one part of the educational program is emphasized to such an extent that some other part is neglected.

Such a program of public relations or interpretation is possible only when the school is performing its educational functions adequately and when those in charge of the program are fully aware of the place and func-

tion of the school in society. (See also STUDENT RECRUITING.)

PUBLIC SCHOOL MOVEMENT—See COMMON SCHOOL MOVEMENT.

PUBLIC SCHOOL (IN ENGLAND)—See ENGLAND AND WALES, EDUCATION IN.

PUBLIC SPEAKING—See SPEECH EDUCATION.

PUBLICATIONS, SCHOOL. There are four main types of school publications: newspaper, magazine, yearbook, and handbook. Although each of these has a specific function, in general all of them serve to unify the school, encourage worthy school enterprises, influence public opinion, provide opportunities for creative work and self-expression, develop school citizenship, foster cordial relations among schools, and record the history of the school.

Newspaper. Although the school newspaper may include a bit of fiction, poetry, and humor, its main function is to publish school news—facts about school people and activities. In general material and form, the printed school paper resembles the commercial newspaper.

School papers are to be found in all grades of the school. The simplest, in the lowest grades, is the "told" paper, in which the news is merely told to a group. The "read" paper is similar to the told paper, but is more definitely organized and is written out and read to the group. "Posted" papers include those written or printed by hand and posted on the bulletin board or the blackboard. Mimeographed and multigraphed papers are common in smaller schools. The printed paper may be either a part (a page or section) of the local commercial newspapers, or it may be a complete school newspaper.

The details of publication—staff and organization, dimensions, number of pages, columning, advertising, etc., vary with the size

PUBLICATIONS, SCHOOL

of the school. In most schools the paper is published once a week; although there are some biweekly and even a few daily papers in American schools. Staff members are appointed by the faculty or its authorized committee, or elected by the school at large. Where the school offers courses in journalism, these classes usually publish the paper as their regular project. Normally a small charge is made for the newspaper, either directly through a regular subscription fee, or indirectly through the activity ticket.

Magazine. The magazine, the oldest type of school publication, is an outgrowth of the creative writing activities of the earlier school, where it was the custom to read student essays, poems, etc., at the meeting of the Literary Society or at public functions, such as graduation. Later this type of material was printed in the form of a school magazine, whose main purpose became the publishing of student-produced literature and art work. Because it appears usually only at intervals of about a month, it cannot present news effectively, although it may include summaries and historical records and accounts.

The main weaknesses of the typical school magazine are that it attempts to include news; it contains too much "humor"—mostly clipped and reprinted; it is apt to be uninteresting or sermonizing; and the material is often written or presented in immature fashion, often the case when the staff itself does all or nearly all of the producing. The present general trend is for the magazine to be best of all-school student writing. The staff contributes relatively little of the literary material, but, with the co-operation of the teachers, encourages writing as well as the production of art materials on the part of the student body. It then evaluates this material and selects and publishes only what it considers to be the best. A second trend is away from regularity of publication; instead of being published every month, the magazine is published only when enough good material has been found to fill it. Hence, it may be issued once a month, once or twice a semester, or even only once a year.

Yearbook. The *annual*, or more accurately the *yearbook*, a comparative newcomer in high school activities, is another of the high school's many imitations of the college.

This publication is historical in character; it presents a history of the school for the year, with particular emphasis upon the senior class, sometimes with secondary emphasis on the junior class. It is composed of writeups, descriptions, biographies, summaries, records, and similar material, with few or no strictly literary efforts. Photographs of students represent an important part of any yearbook.

In general form the yearbook varies from a small, inexpensive, mimeographed or multiprinted booklet to a pretentious, expensively printed, engraved, and bound book. The yearbook is financed by sales of the book, advertisements, assessments of groups represented, and miscellaneous money-raising devices, such as cake sales, shows, parties, etc.

Handbook. The *handbook* or "freshman's Bible" is the youngest member of the school publications group, appearing only within approximately the last twenty-five years. The purposes of the handbook are to supply information concerning the school—its personnel, traditions, rules, organization, activities—and to give counsel and advice. Although designed especially for the new student, in larger schools it serves upper classes too as a reference book of school information.

The material of the handbook may be classified into the following groups: Introduction, Organization of School, Program of Studies, Student Organizations and Activities, and General Usages. The handbook is usually small so that it may be carried easily. Often it is bound in school colors, and is appropriately named and attractively illustrated. It is written in simple and clear style, with short sentences and paragraphs. It is usually given without charge to new members of the school, and often is studied systematically in freshmen home rooms.

PUBLICITY, SCHOOL — See **PUBLIC RELATIONS, SCHOOL**.

PUEBLO PLAN. The Pueblo (Colorado) Plan, or Individual Progress Plan, is a method of instruction devised to overcome some of the difficulties of the graded system, used in most elementary schools, by providing an opportunity for each child to progress in school as rapidly as his ability permits. Under this plan individual instruction is, of necessity, emphasized. Although at times several children in a specific grade may be at the same point of development and may be working together under the guidance of the teacher, usually each child in the class is working on a different assignment while the teacher passes from child to child, directing or assisting, and determining each pupil's readiness for the next assignment.

Since each child is expected to progress at his own rate, and since promotions are based on the ability to do the work of the next grade, promotions to the next higher grade may occur at any time during the school year. Under this plan it is possible for a student with superior mental ability to do the work of two or three grades during one year.

PUNISHMENT. A manifestation of maladjustment is best corrected by eliminating its basic causes. Misconduct is more than an offense that must be punished; it is a symptom to be investigated. The modern parent and teacher will make every effort to guard and promote the child's physical and mental health and to guide him into activities that meet his needs and interests. In this way, the basis for misconduct can be largely removed, and the problem of punishment becomes academic. However, misconduct does occur, even among the best adjusted children, and punitive measures must be taken, especially when the misconduct threatens to disrupt the activity or the morale of the group.

It then becomes necessary to administer punishment in such spirit as to minimize harm and to achieve some positive outcome.

The Psychology of Punishment. Punishment can be interpreted (1) as conditioning and (2) as an application of the law of effect.

(1) Punishment as conditioning involves the association of an undesirable act with an unpleasant consequence. The wrongdoer is exposed to punishment every time he commits the undesirable act. The punishment must follow the act so closely that the two become associated in the offender's mind. Until the conditioning is assured, there must be no exception to this rule. However, these requirements are rarely, if ever, realized in situations outside the laboratory, first, because the punishment usually follows detection rather than commission of the offense (thus children are punished not when they cheat but when they have been caught); secondly, because it is difficult to punish wrongdoing as regularly as conditioning would require (many offenses go unnoticed; others are ignored because of the existence of more pressing matters at the time the offense is committed); thirdly, because punishment is useful only as a means of eradicating a specific wrong response—it has little value as an incentive for the development of the correct response.

(2) A slightly different explanation of the psychological use of punishment is obtained by applying Thorndike's law of effect. Punishment is decidedly an annoying state of affairs and it is hoped that the infliction of punishment will reduce the likelihood of a repetition of the offense. The limitations of punishment justified by the law of effect are similar to those affecting punishment used as conditioning. Experimental evidence indicates that punishment may inhibit undesirable behavior, but that it can hardly be used to facilitate the child's positive adjustment to his environment. Recent investigations demonstrate that punishing the incorrect response is of little value to the learning process—in fact, in some experiments the repetition of the incorrect response did more to fix that response than the infliction of punishment served to weaken it. Positive incentives are far superior to punishment in strengthening proper responses.

The Basis for Punishment. The pre-

PUPIL ACTIVITY

R. PULLIAM, *Extra-Instructional Activities of the Teacher* (Doubleday, Doran and Co., Garden City, New York, 1930).

W. R. SMITH, *Constructive School Discipline* (American Book Co., New York, 1936).

PUPIL ACTIVITY.

Learning is an active process. The degree to which the student participates actively in an experience indicates the extent to which he can learn from that experience. Learning is thus influenced only indirectly by the teachers' activity. Viewed from the standpoint of pupil activity, no teacher can ever teach a child anything; the teacher's function is to guide the child in learning.

The importance of pupil activity was discovered rather than invented by modern educators. Learning was an active process even when that fact was not recognized by teachers. If education a century ago placed so little stress on the nature of pupil activity, it was partly because our predecessors had so much faith in comprehension and memory. To them, knowledge was both virtue and power. If the student understood the rules of grammar, it was assumed he would speak and write grammatically. If he knew the facts of history, it was taken for granted that he knew how to study and interpret history. Today we all know what only some teachers had learned intuitively in the past: the child learns best when he participates actively in the process. If he is to learn to speak before a group, study of the principles of rhetoric is an inadequate substitute for the actual experience of speaking in public.

The older schools used pupil activity, else their students would have learned little, but they ordinarily restricted the field of activity to subject matter that was to be learned, and the activity consisted largely of comprehension and memorization. Today we take for granted that students should help select and plan the activities to be conducted by the class and that they should participate in the evaluation of these activities. Similarly, increasing emphasis is being placed on the appreciational and applicational aspects of the subjects studied in school. We believe today that the child can learn to assume responsibility only by actually having experiences that involve his assuming responsibility.

dominant aim of the punishment, whether it be retribution, deterrence, or correction, will determine the spirit in which punishment is administered; it will determine also when an occasion makes punishment necessary and the kind of punishment used. Punishment as retribution is unjustifiable in schools, for it assumes "contrariness" to be the real cause of the child's misbehavior. The teacher should be above the level of mere vengeance; his actions must show that the only reason for the punishment is that the misdemeanor is against the best interests of the child and of the group. Punishment as a deterrent may be effective in keeping some would-be offenders from behaving in an anti-social manner, but there are more effective ways of preventing misdeeds. Teachers who use punishment as a deterrent sometimes punish one offender severely as an example to the others in the class. This practice is fraught with danger, since martyrdom achieves the opposite effect from that sought through persecution. When punishment is used as a corrective measure it is seen not as a separate entity but as part of the total educative process. The specific offense becomes secondary as the teacher adjusts the nature and degree of the punishment to the child. It is used only as one means of removing a tendency to unsocial behavior. The emphasis is not on the "crime" but on the "criminal"; punishment does not fit the crime, but fits the criminal so well that he ceases to be a criminal.

When punishments are administered effectively they satisfy the following criteria: They aim at modifying the child's behavior and not at punishing him for past misdeeds. They are not regarded as constituting the complete treatment for problem behavior. They assist the student in making a sound adjustment to his environment. They are used only when the child fails to respond to more positive appeals and incentives. They are adapted to the child. They are not unduly severe. They leave no residue of antagonism or resentment. (See CORPORAL PUNISHMENT; NATURAL CONSEQUENCES.)

It is unfortunate that pupil activity is sometimes interpreted so narrowly that it becomes synonymous with motor activity. Pupil activity in swinging hammers and shouting youngsters does not necessarily yield any appreciable educational value. On the other hand, a class that is listening to a lecture may be learning a great deal if the students are listening in order to find the answers to questions they have formulated. When learning is explained in terms of pupil activity, the expression refers as much to mental and social activity as to physical activity. (See ACTIVITY PROGRAM.) F.A.B.

PUPIL-CLOCK-HOURS. The term *pupil-clock-hour* differs from the broader term, *service load*, in that the former does not include all the service rendered by a teacher in a school system. It is, however, the most widely accepted method of measuring the teaching load.¹ In order to calculate the number of pupil-clock-hours per week that a teacher teaches, we multiply the average number of pupils taught per day by the average number of hours of instruction per day by the number of days taught each week. Thus, if a class of 20 pupils meets 5 days a week for 50 minute periods each day, the number of pupil-clock-hours per week for this class is $20 \times 5 \times 50$ or 88.33. If a teacher meets six

60

such classes a day, then his load in terms of pupil-clock hours a week is $20 \times 5 \times 50 \times 6$

60

or 500.

The load of the elementary-school teacher, as measured by the above formula, is larger in cities than it is in rural communities. It increases as the population increases. White teachers carry much lighter loads in terms of pupil-teacher ratio and class size than do Negro teachers. The trend, however, between 1931 and 1936 was towards a decrease in class size for kindergartens and elementary schools of city school systems.⁴ From an examination of the reports for schools of rural school systems, one finds approximately the same situation. Most studies show the pupil-teacher ratio to be heavier for women teachers than for men, but men spend approximately

50 per cent more time in other school activities;³ thus, bringing out the failure of pupil-clock-hours and pupil-teacher ratio to indicate the actual load of the teacher.

In applying this measure in the National Survey of the Education of Teachers, the number-of-pupils factor was omitted from the formula with the result that the teaching load was measured in teacher-clock-hours. The clock-hour class load per week was found to be lightest in medium sized cities. The median loads for both junior and senior high-school teachers in 1930-31 were between 25 and 30 clock hours a week. There was little relationship between size of community and the teaching load of secondary school teachers. The median load of college and university instructors for the same period was 15 teaching clock hours a week. Teachers in junior colleges and teachers' colleges carry the heaviest clock-hour loads,² of all college and university instructors. (See TEACHER LOAD.)

PUPIL PERSONNEL—See CHILD ACCOUNTING; GUIDANCE.

PUPIL STATION — See BUILDINGS, SCHOOL.

PUPIL-TEACHER RATIO. The pupil-teacher ratio of a school is computed by dividing the total number of pupils enrolled by the number of teachers. Accrediting associations employ this measure as one index of the teaching load of a secondary school and usually set the maximum at thirty pupils to one teacher. If comparisons among schools are to be valid, it is necessary that the same procedure be employed in defining a teacher. Therefore, some arbitrary rule is usually followed in a particular situation to determine how the principal, librarian, supervisors, etc., are to be counted.

PUPPET SHOWS — PURPOSEIVE PSYCHOLOGY

The student-teacher ratio is sometimes used to evaluate the teaching load in colleges and universities. However, it is relatively unsatisfactory as such an index, since the complexity of an institution of higher learning makes it difficult to determine accurately the number of instructors and students upon which to base the ratio. For example, many college teachers combine teaching with research or administration and many college students carry only part of a full schedule. Moreover, some college classes are administered in small seminar sessions while others are conducted in large lecture halls. As a result, the computation of the student-teacher ratio may yield a meaningless number that does not indicate how many students the average instructor at that institution does teach.

PUPPET SHOWS—See **DRAMATICS**.
L.M.C.

PURCHASING, SCHOOL. The procurement of supplies and equipment for schools by payment of cash or value. In making school purchases it is helpful to have a standardized list of supplies and equipment to serve for basic needs. This can be coupled with request forms to be used by members of the staff in indicating their needs, and with inventory records of supplies and equipment on hand.

Among the plans employed in actually making purchases are purchasing without much reference to prices or quality of articles from other firms; purchasing after checking with other firms but not letting bids; and purchasing on bids. There is great variation in the definiteness of the specifications on which the bids are supposed to be made. Thousands of dollars are wasted each year by small schools for the privilege of buying their own supplies. Since the individual school district is usually too small to obtain the most advantageous prices on school supplies and equipment, cooperative purchasing by several districts can be used as a means of reducing costs. Cooperative buying for schools may be the result of voluntary extra-legal effort or of legislative enactments. In California, which provides by law for county-wide purchasing of school supplies, it was found that cooperative buying of school supplies effected an average savings in some counties of approximately 50 per cent. North Carolina and Delaware have established a state purchasing agency.

The type and cost of materials as well as the geographical location of the district are factors affecting purchasing procedures. Usually the more detailed and standardized the specifications, the better is the purchase. Obtaining bids on small items and limited quantities is a waste of time and money. Governmental regulations, such as price ceilings and priorities, markedly affect purchasing procedures.

C.A.D.Y.

PURPOSEFUL ACTIVITY. About the time the project method appeared, a number of words were used to describe the qualities associated with it. One of these words was "purposeful." This adjective directed attention to the inner worth and feeling attached to the undertaking by the pupil. In other words, the pupil felt the purpose behind the activity was his; it was his choice; it was his will supporting the job. The contrast here was with schoolwork that was assigned and required by the teacher, and done by the pupil without any choice or share on his part. Purposeful activity comes under the general heading of motivation. Mental-set is another term meaning about the same as purposeful. Each term implies that the learner will be better if the learner has the right attitude toward his work. If the learner has a real purpose—his purpose—as the stimulating factor, he will throw himself into the task. The average pupil who purposes to build a piece of furniture because he needs the furniture admittedly applies himself and learns more about woodwork than the pupil who makes an article because the teacher demands it. It is inner determination as opposed to outside dictation.

Initiation of the purpose can rest with the teacher or it may come directly from the pupil. The important consideration is that the pupil himself feels the worth of what he is doing and learning. (See **INCENTIVES, PROJECT METHOD**.)

QUESTIONNAIRE METHOD. The questionnaire method refers to the construction and utilization of a form which is designed to secure responses to certain questions. The form, or questionnaire, may be used to get at factual information, interests, attitudes, opinions, and judgments. Opinions may be treated as facts, in the sense that their existence may be factually established. But opinions about facts must not be confused with the facts themselves.

The questionnaire method is generally dependent upon the voluntary cooperation of the persons who are questioned; its validity is dependent upon the degree to which the persons questioned form a representative group and upon the truthfulness of their answers. To secure cooperation it is frequently advisable to utilize some form of motivation or appeal. This may be coupled with a frank request for truthful and sincere replies. Anonymity frequently leads to freer responses.

It is unfortunate that the widespread misuse of the questionnaire has resulted in its being generally discredited as a source of data. Among the misuses, perhaps the most devastating are their use in connection with insignificant investigations, the inclusion of trivial questions, and the request for informa-

tion which is available in other sources. These practices have alienated many persons and worked to the detriment of qualified investigators. In addition, there are technical limitations which may operate to destroy the reliability and validity of questionnaire data and thus produce misleading results. These abuses and limitations may be overcome through the proper construction and administration of the questionnaire. The following precautions, among others, should be carefully observed. (1) The technique should be used only when there is no other feasible means of securing the required information. (2) Every question should be carefully checked for significance and lack of ambiguity. (3) Technical terms which may be variously interpreted should be adequately defined. (4) Long, involved questions should be avoided. (5) "Leading questions" which suggest or otherwise hint at the expected or favored answer should be scrupulously examined and either removed or reworded. (6) "Cross-checking questions" may be worth including in order to check on the consistency of the response. (7) The mechanical features should provide a pleasing format with adequate space for the answers. (8) The responses or entries required on the form should be of as simple types as possible. (9) The replies should be in a form capable of necessary statistical analysis. (10) The questionnaire should be as short as possible, since excessive time required to answer questions leads to careless responses, omission of items, and fewer returns. As a final precaution, the questionnaire should be subjected to one or more preliminary trials with representative samplings of the individuals for whom the questions are designed in order to detect limitations that might otherwise be overlooked. (See **RESEARCH, EDUCATIONAL**)

QUESTIONS AND QUESTIONING

QUESTIONS AND QUESTIONING.

The expression "question and answer method" has been used generally to mean the practice of developing a lesson or carrying on classroom activities by means of a series of questions and answers. Such a procedure has often resulted in routine testing or a mere recital of facts amounting to little more than lesson-learning. In modern practice, teachers plan their courses upon such bases as topics, problems, projects, or units, so that pupils have opportunities to engage in a variety of activities essential to the attainment of the desired outcomes or goals. These activities can be organized effectively by the use of such different procedures as recitation, discussion, problem-solving, practice or drill, directed study, etc. Questioning has a place in each of these teaching procedures and a teacher's success depends to a considerable degree upon his ability to use questions effectively. Proficiency in questioning rests primarily upon a thorough understanding of the ways in which questions may be used to stimulate and direct the activities necessary to the attainment of the desired goals.

While it is evident that questioning is used chiefly to discover how thoroughly the pupils have prepared their lessons, it is used also for many other purposes: (1) to discover (diagnose) weaknesses of a class and individual pupils, (2) to motivate pupils through careful and skillful checking of preparation and achievement, (3) to stimulate interest and provide motives by directing attention to important points and phases of work, (4) to direct and stimulate the thinking of pupils and improve their ability to organize and think through what is being studied, (5) to clarify understanding of the organization of work and material studied, (6) to provide practice or drill, (7) to discover interests of pupils, (8) to stimulate the formation of attitudes, interests, appreciations, and habits of conduct, and (9) to set up and direct classroom procedures involving the work of units, problems, projects, etc. To fulfill these purposes the teacher must necessarily adapt his questions and technique of questioning to the ends in view. This adaptation requires careful consideration of the outcomes, the kinds of questions, and the techniques of questioning.

In determining the nature of questions that should be used there are a number of important points to be kept in mind. The first is that the questions should conform to the purpose for which they are used. Questions to test knowledge of facts require purely memory or recall responses, while questions to test ability demand analysis, comparison, evaluation, etc. Second, questions should present a challenge which stimulates responses vitally related to the objectives. To accomplish this the relative importance of topics and problems must be considered. A question may conform to the purpose for which it is used and yet present no real challenge to stimulate and direct thinking. Another consideration is that the wording of a question should be in good English, clear, brief, and definite to avoid need for repetition or clarification and to prevent waste of time in getting at the objective. The questions should not follow too closely the wording of the textbook, and the sequence of questions should be independent of the organization of the text, lest pupils try only to remember what is in the book at the expense of independent thinking on the subject. Finally, questions should be adapted to the ability and experience of the pupils to whom they are addressed. The use of words unfamiliar to pupils is one of the frequent violations of this principle.

The kinds of questions may be classified into two main divisions, (1) memory questions, involving recall, and (2) thought questions, involving reflective thinking. Thought questions may be divided roughly into two types, namely, those questions necessitating recall followed by an evaluation of the facts or some other relationships, and those questions calling for an evaluation of facts or conditions furnished the pupil.

The technique or procedure used in questioning is important. In developing topics or problems the questioning should be planned in such a way that pupils see the significant relationships concerning the topics or problems. To accomplish this the teacher should select the important relationships to be developed and then plan the key questions which are to indicate these relationships, thus unifying and integrating the pupil's work and his knowledge. This use of questions gives the pupil a meaningful perspective he would

not be apt to get through fragmentary questioning. There are other points of good procedure in working with groups of pupils: (1) Questions should be asked in a natural, interested, and conversational tone. (2) Questions should be addressed usually to the entire class before indicating which pupil is to answer. (3) As much as possible, all pupils should be brought into the discussion. (4) The pace of the questioning should be adapted to the particular objectives in view, thus drill questions may be asked in rapid sequence but thought questions should allow time for reflection and for organizing the answer. (5) The distribution of questions should be adapted to individual differences and needs. (6) The practice of repeating the teacher's questions and the pupil's answer should be avoided unless there is a definite reason for repetition.

Teachers have also learned to avoid such poor practices as the use of (1) leading questions that suggest the answer, (2) catch questions, which are usually irrelevant, (3) indefinite, "Discuss," and "What about" questions, and (4) meaningless questions, such as "isn't it?" "didn't he?" etc., at the end of statements.

Questioning has been referred to as an art, an art that distinguishes the good teacher from the mediocre one. As with all arts, superior achievement cannot be attained merely by learning rules, although the intuitive or deliberately acquired understanding of basic principles should improve performance. Preservice courses for teachers and books on methods of teaching have placed so much emphasis on the so-called rules of questioning that many a young teacher is under the mistaken impression that his skill in using the question as a teaching procedure depends on the regularity with which he follows such a suggestion as that questions be addressed to the whole class before calling on the student who is to answer. These guiding prin-

ciples are helpful, but they are far from adequate for indicating how the teacher's questions can become more significant and more challenging for his students. When we turn to Socrates as a classic illustration of the use of the question as the major instructional procedure, it is not because Socrates always waited fourteen seconds before calling for the answer. If the teacher is to become a skillful and a stimulating asker of questions, he must have so thorough an understanding of his students' mental processes and so complete a mastery of the area being studied that he can select and organize his questions effectively.

Too much emphasis has been placed on the questions which the teacher asks rather than on those which the student asks. The asking of questions often becomes part of a classroom ritual when the teacher asks questions in order to see whether the pupils can express the answer which the teacher has already formulated in his own mind. It should be part of the teacher's aim to see that classroom experiences are so meaningful that it is the students who ask most of the questions. "The Questioning Age" is described by psychologists as the period when the child is from three to six years of age. Significantly, it is in the years before the child enters school that he asks most questions. If the child's questions are welcomed and encouraged by teachers and parents, every age should be a "questioning age"; in fact, the longer a child has been at school the more frequent and significant should be his questions. RADIO EDUCATION, ADVISORY COMMITTEES ON.

Several groups have been organized to assist the teacher in the use of radio as an educational instrument. Among the most active of these is the Federal Radio Education Committee (FREC), United States Office of Education, Washington, D. C. This committee was organized in 1935 by the Federal Communications Commission to eliminate controversy and misunderstanding among educators, and between educators and the broadcasting industry. The FREC has sponsored research on significant problems in the utilization of radio in the schools and initiated the Educational Radio Script and Transcription Exchange. It publishes the monthly *FREC Service Bulletin*. The Radio Division of the United States Office of Education assists local radio research and program production, lends scripts and recordings, and serves as a central clearing house for all kinds of information concerning various aspects of educational radio. It cooperates closely with the FREC.

For eleven years the National Committee on Education By Radio served as one of the principal advisory committees on the use of educational radio. This committee has now discontinued its activities, but copies of its final report, *Tune In For Education*, are still obtainable from Room 308, One Madison Avenue, New York, N. Y.

In 1942 the Association for Education by Radio was formed by educators interested in the school use of the radio. It holds annual meetings and issues the *Journal of the AER*. Headquarters are at Rocky Mountain Radio Council, Denver, Colorado.

RADIO IN EDUCATION. Radio has added immeasurable opportunities for variety and sparkle in teaching. It has introduced into

the classroom new authoritative voices, dramatic presentations, and ringside seats to world events in the making. The teacher of English has been able to bring presentations of the great plays, readings by contemporary poets, and examples of good speech. The science teacher now has available science forms, news of inventions, and recreation of dramatic episodes in the fight against disease. The music teacher has especially good courses in music appreciation and stories of great composers to present to his class. The social science teacher has been indeed fortunate in the wealth of current material, historical dramas, and broadcasts of great events. The radio promises much for the future of education, but much of its promise remains yet to be realized.

Among the difficulties in using a radio in the classroom are the following: desirable programs do not come at an hour when they may be utilized for class work; programs often do not gear into the sequence planned for a particular course; many schools are not properly equipped for radio reception; and efficient techniques for the utilization of the radio have not been developed. The experimentation which has been conducted with this new teaching tool has led to the conclusion that the best programs for use in the schools are those which send out announcements of their programs well in advance (See *Teachers Manual*, Columbia School of the Air of the Americas and NBC Inter-American University of the Air), provide the teacher with a synopsis of the material to be presented, and furnish suggestions for integration of the program into the school curriculum. There is a place for the use of the broadcast of such unusual events as a presidential inauguration or an address before Congress. The school program should be flexible enough to make room for such a broadcast. There is, too, a place for the assignment of listening to such programs which come in evening hours, as "Cavalcade of America." This type of listening is

RANDOM SAMPLE — RATE BILL

difficult to control. An increasing number of teachers are overcoming this difficulty by purchasing transcriptions of such programs and playing them to their classes at the time when they will contribute most to desirable learning. (See AUDITORY AIDS.)

Still other school systems have attempted to solve many of the problems of radio utilization by setting up school broadcasting stations. In the city of Cleveland, the School Board broadcasts regular lessons, and in New York City, the Board of Education maintains its own studios (WNYE, a division of WNYC, the municipal station). Instructions and supplementary aids in the form of slides, maps, readings, and the like are sent to the teacher at the beginning of the term along with a synopsis of the program. The radio lesson then becomes an integral part of the child's experiences in connection with the local curriculum. It supplements the teacher and works hand-in-hand with him. Schools which are not able to set up regular broadcasting stations have used their central sound systems as a broadcasting unit for the various classrooms, utilizing student, faculty and other local talent, or using recordings.

Out of the experimentation conducted to date the following general principles have been evolved: (1) Purchase a good standard receiving set. (2) Select programs carefully, avoiding those which contain too much extraneous material. (3) Conduct the radio lesson in a natural classroom setting where maps, pictures, and other supplementary aids may be utilized. (4) Discourage note taking during dramatic presentations; substitute the writing of summary notes at the close. Note taking is valuable when a plan or program of action is being presented. With younger students it has been found best to have the teacher outline the program on the blackboard. (5) Follow up the broadcast with further activities which will clarify and enrich radio material. (6) Hold the students responsible for radio material and constantly evaluate the contribution of any particular program or series of programs. W.H.H.

RANDOM SAMPLE—See SAMPLING.

RANGE—See VARIABILITY.

RANK ORDER. Rank order is the number assigned to individuals in a group when they are being counted from the top down, the highest individual receiving a rank of one; although sometimes the counting is done, arbitrarily, from the bottom up, giving the lowest person a rank of one. If there happen to be two or more persons tied for any rank position, the customary tie-breaking procedure is to consider all the rank positions that would be occupied by the tied individuals, without regard to which rank belongs to whom, then to assign to all tied individuals alike the mean of the ranks they occupy. For example, if two tied individuals come just below a rank of 7, they would normally occupy ranks 8 and 9. Not knowing which is which, we assign the rank of 8.5 to both. The next person below them then has a rank of 10. Three persons tied for ranks 11, 12, and 13, should all be called 12 and the next lowest person 14. At the bottom of the list the last person should have a rank of N , the number of individuals in the list, unless two or more persons are tied at the end of the list. This serves as a rough check upon the correctness of ranking, particularly in dealing with ties. J.P.G.

RAPID ADVANCE CLASSES — See CLASSIFICATION OF STUDENTS.

RATE BILL. The rate bill or rate tax was widely used in the early days of school support, particularly during the eighteenth and early nineteenth centuries. In this unique form of cash support, pupils were assessed on a per capita basis to cover the costs of schooling above the funds on hand. Thus the amount to be paid by pupils or their parents was pro rated.

The following is an illustration of how the rate bill was applied locally:

RATING SCALE — RATIONALISM

Cost of education for school year.....	\$1,100.00
Raised locally by such means as taxation.....	500.00
To be raised by rate tax.....	600.00
Number of pupils in school (40).....	\$ 15.00
Rate per pupil (\$600/40).....	C.A.D.Y.

Later, this system gave way to complete public support.

RATING SCALE. A rating scale is an instrument consisting of a series of traits relating to the achievement, character, or personality of an individual or to the attributes of a thing, with provision for recording the judgment of the rater as to the degree to which each trait is possessed. An effort is usually made to assign numerical weights to the different traits according to their relative importance and to indicate by descriptive words or phrases the varying degrees to which each trait is manifested. Rating scales may include such questions as 'To what extent does this student participate in campus social activities?' — regularly — frequently — occasionally — rarely.

Since an accurate judgment can be made only when the judges have a clear picture of what is to be rated, the trait under consideration must be defined carefully. *Operational definitions* (q.v.) are helpful. *Graphic rating scales*, too, are superior to ordinary rating scales and check lists because each step on a graphic rating scale is defined by descriptive phrases. A typical question on a graphic rating scale is: *To what extent does this student participate in social activities?* — regular participant in social activities and leader and initiator of many social activities — an occasional leader — frequent participant but rarely if ever a leader — occasional participant — never a participant.

The judges must have had many opportunities to observe samples of the behavior being rated. In this way errors in rating, which result from lack of familiarity with the trait in question, may be reduced. Other errors in appraisal arise from the failure to eliminate personal elements which enter into the judgment. The term *personal equation*, originally developed by astronomers to characterize individual differences in recording observations, now describes any personal difference in an individual's bias or behavior. Thus, the judge's personal equation enters into appraisals made by means

of a rating scale. Some judges consistently rate individuals either too high or too low, thereby introducing a constant error in the ratings they make. Others are unwilling to give ratings which indicate extreme superiority or inferiority in a given trait, tending to rate all individuals as average.

The validity of the ratings is often reduced by the *halo effect*, which refers to the influence the rating on one trait exerts on the rating of a second trait. Thus, if applicants for a position are rated for appearance, intelligence, poise and health, a person rated high in appearance may be rated higher in the other traits than he deserves. The reliability of ratings may be increased by combining the judgments made by several persons. Ordinarily, using from three to five judges will give satisfactory results. As has been indicated above, greater reliability is attained when the trait to be rated is divided into several subtraits, which are described concretely with separate ratings given for

RATING SCALES, TEACHERS — See C.C.R. and J.J. TEACHERS, RATING OF.

RATIONALISM. In a very broad or even loose sense, rationalism applies to any commitment to use reason in the affairs of life. It is in a more restricted sense, however, that rationalism derives its usual meaning. Here it refers to an exclusive dependence on reason, especially *a priori* reason, as the chief source and final criterion of knowledge. In this sense it strikes out on the one hand against knowledge predicated on authoritarianism or unreasoned religious belief and on the other hand against knowledge which is based on empiricism.

Part of the enlightenment in the seventeenth century, rationalism was both effect and cause of the transition from authoritarianism to individualism, from classicism to modernism. Although starting with systematic scepticism, it aimed at eliminating uncertainty from knowledge. This it proposed doing by discarding all presuppositions and accepting in their place only that which was clearly and distinctly intuited by or immediately self-evident to reason.

This philosophy had its chief influence among Catholics in the Oratory and Port

Royal schools and among Protestants in the schools influenced by Pietism and Deism. There the result was to decry the conventional mode of learning on authority and to institute in its stead the method of insuring that children clearly understand what they learned. While the syllogisms of Aristotle were recognized for the dialectical training they afforded, it was denied that they were a valid means of gaining new knowledge. Consequently schools affected by rationalism were usually favorable to the introduction of the new scientific studies. Furthermore, they emphasized the vernacular and made their discipline mild and reasonable.

Useful as rationalism was as a protest against the old order and in developing people who could think freely about the new, it became formalized and decadent in the schools of the eighteenth century. Its chief influence was felt in the education of the upper classes with their affected superiority. Here everything was viewed in the cold light of reason. If on the one hand this involved teaching a full control of one's physical emotions, on the other hand it prevented unrestrained enthusiasm in one's studies. Consequently, perfection of form and polite manners prospered at the expense of sincerity. Moral education consisted of punctilious conformity to a strict code of conduct. The attendant lack of seriousness found further expression in a curriculum which stressed worldly wisdom and only a smattering of solid knowledge.

Against an education which had become so rational as to have turned cynical, selfish, and contemptuous of the masses, it is small wonder that the fresh spontaneity of naturalism was so heartily welcomed as an antidote. But naturalism and subsequent intellectual movements in the nineteenth and twentieth centuries were not so much anti-rational as they were attempts to achieve an accommodation between the rational and the empirical.

J.S.B.

RATIONALIZATION. Rationalization is a kind of prevarication or falsification in which, knowingly or unknowingly, excuses, explanations, or motives that are not the true ones are offered to justify one's conduct, beliefs or opinions to one's self or to others. A more or less plausible explanation, which

does not seem like simple lying, is offered. Thus the pupil attributes his low grades to the "cribbing" of the other pupils or the partiality of the teacher, instead of to his own lack of application or of ability.

Rationalization may assume various forms, such as telling "white lies;" resorting to hypocrisy; withholding relevant facts; distorting, exaggerating or embellishing facts; inventing silly or ridiculous answers to divert attention or conceal the underlying motive; developing an illness or neurosis as an excuse for shirking detested duties—in fact, all kinds of defense mechanisms may be regarded as different forms of rationalization.

People try to rationalize away their difficulties because they want to camouflage their real feelings or motives, to avoid giving offense by telling the bald truth, to avoid performing distasteful tasks, to enhance their egos by rationalizing their motives on a higher plane than is justified, and to use a type of deception that often works. The motive sometimes operates automatically through force of habit or "buried complexes."

The objections to rationalization are manifold. At best it represents efforts to dupe others and to deceive one's self. It is a great foe to general educational and intellectual growth and socialization because it does not encourage the attitude of intellectual honesty, open-mindedness, and unprejudiced objectivity. It is an admission of failure to grow up and achieve intellectual independence. It is a form of infantile fixation or regression.

RAW SCORE—See SCORES, CONVERSION OF.

READING DISABILITY. An individual whose ability in reading is definitely below normal expectancy for both his age and his general intelligence is said to have a *reading disability*. Although in general there is a fairly close relationship between intelligence and reading comprehension, severe reading

READING DISABILITY

disabilities may be found in children of normal or superior intelligence.

Comparisons of groups of reading disability cases with groups of normal readers have shown that no one factor is responsible for reading disability. In an individual case causal significance may be attributed to one or, more frequently, several of the following: (1) lack of readiness when first given instruction in reading, followed by inability to make up the lost ground and the development of unfavorable attitudes towards reading; (2) physical handicaps, including defective vision, defective hearing, and endocrine abnormalities; (3) generally retarded language development, usually related to a marked cultural handicap or a speech defect; (4) confused directional tendencies, resulting in failure to develop systematic left-to-right habits of observation in word study and reading; (5) poor emotional adjustment accompanied by inability to maintain sustained effort and attention, and sometimes by a special aversion to reading; (6) accidental interference with the learning process through frequent or prolonged absence, or the disrupting effect of frequent change of school or teacher; and (7) poor instruction.

Most cases of reading disability are capable of marked improvement with appropriate special instruction.

Remedial reading is a descriptive term applied to all methods of teaching reading which are intended specifically to improve the proficiency of retarded readers. The suggestion that remedial efforts made in a regular classroom situation should be called "corrective reading" and that the term "remedial reading" should be reserved for work with individuals and small groups has not been generally accepted.

Good procedure in remedial reading starts with careful diagnosis. The pupil's ability in both silent and oral reading is thoroughly analyzed to locate important weaknesses in word recognition, fluency, and comprehension. For this purpose both standardized tests and informal procedures are used. A study is made of the child's mental ability, physical condition, home environment, emotional condition, and school history to discover the probable underlying causes of retardation. On the basis of this analysis a

plan of instruction is worked out to meet the child's needs; wherever possible the causes of retardation are removed.

It is important in remedial reading to direct the instruction to the child's reading level. If a sixth grade child is weak in basic skills usually acquired in the primary grades, it is necessary to re-teach those skills. In extreme cases it is sometimes essential to start over again at the beginning of first grade work. Materials used should be at, or below, the pupil's grade level in reading ability, and difficulty should be increased gradually as the child improves.

Another major requirement is adequate motivation. Retarded readers need to be given confidence in their ability to learn; encouragement, praise, and the dramatization of improvement by means of progress charts are important. The reading material used should be carefully chosen on the basis of interest appeal as well as difficulty. Monotony should be avoided by the use of a variety of reading activities, and when drills are necessary they should so far as is possible be enlivened by treating them as games or contests.

With non-readers and extreme cases of reading disability, the major problem is usually the teaching of word recognition. Try out lessons may be utilized to determine whether the pupil is likely to make most rapid progress with a visual, phonic, or kinesthetic method or with a combination method.

The kinesthetic method is a procedure for teaching word recognition to extreme cases of reading disability. The essence of the method consists in writing a word in large script and having the pupil trace over it again and again with his fingers touching the copy until he can write the word from memory. The printed form of the word is taught by presenting it on a card which also contains the script form. After words have been learned, flashed exposures are used to develop speed in recognition. Connected reading material is introduced only after the pupil has learned all the words contained in that material. The method requires individual tutoring and is ordinarily used only when the pupil has shown marked inability to learn by visual or phonic methods. It is frequently employed as a supplementary method for teaching words on which pupils have special difficulty.

For moderately retarded readers in the upper grades and secondary school, common remedial problems are developing an interest in reading, increasing reading vocabulary, providing practice in specific types of silent reading, and improving rate of reading. Good remedial programs at these levels usually provide a balance between extensive reading of easy recreational materials and practice exercises of various kinds to overcome deficiencies in comprehension and rate. A number of special work-books and remedial textbooks are available which can be used profitably in such programs.

While the extreme cases usually require more individual attention than can be provided in a classroom situation, moderately retarded readers can be taught successfully in classes of ordinary size. Special provisions for remedial work may be made by organizing a remedial reading class under a specially trained teacher or by classifying pupils into homogeneous groups for reading instruction. Teachers of remedial classes usually divide the class into smaller groups for instruction or provide individualization by means of differentiated assignments. READING, EXTENSIVE. For many years there has been a division of opinion concerning the relative merits of extensive and intensive reading. Extensive reading means wide reading in a variety of sources, while intensive reading means a program of careful and detailed study of a limited amount of reading matter. In the teaching of English the conflict has been between those

in favor of careful study of a few classics and those advocating wide but relatively superficial reading from a large list of approved titles; in the social studies the issue is the relative importance of the textbook as compared with collateral and supplementary references; and in the teaching of reading itself difference of opinion exists regarding the stress to be placed on readers as compared with other sources of reading materials.

The main arguments in favor of extensive reading are that (1) it provides richness of vicarious experience from which the reader develops a wealth of vocabulary and useful concepts in a natural way, (2) it makes possible a close adaptation of instruction to the individual differences among the pupils, and (3) it tends to arouse favorable attitudes towards learning and aids in the development of desirable intellectual interests. When relied upon exclusively, extensive reading is subject to criticism on the grounds that (1) it fails to provide a core of common experience for the group; (2) the pupils may get insufficient practice in careful, accurate reading; and (3) the organization and logical structure of the subject matter may be obscured by interesting but largely immaterial details.

The trend of expert opinion in recent years has been to emphasize the importance of extensive reading, but not to the exclusion of intensive reading. In any teaching situation the desirable balance depends upon the nature of the subject, the ability and maturity of the pupils, and the availability of suitable reading materials. READING, EYE MOVEMENTS IN. As a person reads, his eyes move along a line of print in a succession of alternating quick movements and brief pauses. The pauses, which are called *fixations*, last only a fraction of a second each. The amount of

READING INTERESTS

print which a person can perceive during one fixation is called his *recognition span*. The quick movements between fixations are called *saccadic* movements. From the end of one line to the beginning of the next, the eyes make a rapid, continuous diagonal movement called a *return sweep*. *Regressions* or backward movements are usually the result of a need for re-reading, and are not made frequently by good readers.

As a child improves in reading, the average duration of his fixations decreases, his recognition span becomes wider, he makes fewer fixations and fewer regressions, and his rate increases. At the end of the first grade an average child makes about two and a half fixations to a word and makes a regression about every other word, reading at a rate of approximately a word a second. Improvement in these characteristics takes place rapidly during the first four grades and at a slower rate after that. A college student averages between one and two words to a fixation and makes about one regression a line, reading at a rate of about six words a second.

In oral reading, an effective reader's eyes stay a few words ahead of his voice, thus giving him a basis for proper phrasing and expression. The distance between the last word a person looks at and the word he is pronouncing is called his *eye-voice span*.

Eye-movements during reading can be accurately photographed with special cameras, in which a beam of light is reflected from each eye onto a continuously unrolling film. Such photographs allow an exact measurement of rate of reading, duration of fixations, etc., and also clearly reveal any irregularities that may be present in eye coordination. Less accurate but practically useful observations of eye-movements can be made by watching a person's eyes as he reads (through a small hole in the reading matter, across the top of the book, or in a mirror placed at an angle on the table.)

There has been a difference of opinion as to whether poor eye-movements are a cause of poor reading ability or whether they simply reflect the fact that the individual reads poorly. It has been amply demonstrated that the eye-movements of a good reader show marked temporary deterioration when he reads material that is very difficult for him. The implication is that the eye-movements

reflect rather than cause the reader's ease of comprehension. In remedial work in reading, major attention should be devoted to the improvement of comprehension and fluency rather than to the improvement of eye-movements as such.

READING INTERESTS.

Although individual differences in reading interests are great at every age, the results of many surveys have demonstrated the existence of general trends about which there is marked agreement.

Children beginning to read enjoy short, fanciful stories involving talking animals, fairies, and other mythical creatures; they also like realistic stories about children, with elements of surprise and humor. Interest in the fanciful usually reaches its peak at about the age of eight and then gradually declines. Boys become absorbed in adventure and mystery tales, fictionalized history and biography, mechanics, science and invention, and material related to hobbies. Girls enjoy sentimental stories of home and school life and usually develop an interest in romantic fiction between the ages of eleven and fourteen. They share the boys' liking for mystery and adventure but usually do not care for reading related to science and invention; the boys, on the other hand, tend to ignore the human interest stories which are feminine favorites. Nearly all children enjoy comic strips and magazines, some of which meet reasonable standards, although others are definitely objectionable. There are frequently marked differences between what children marked read and what teachers and librarians recommend. Commonly the greatest quantity of voluntary reading is done at the ages of twelve and thirteen. The preponderant interest in fiction continues through the high school and college years but is influenced by increasing maturity of taste and by the broadening and individualization of interests. Bright children tend to read more, have a wider range of interests, and are usually a year or two ahead of the average child in interest maturity. The mentally slow child

READING, METHODS OF TEACHING

reads less yet generally has preferences which are more mature than those of younger children of his mental level. The problems of providing material for the retarded reader which is easy enough and still suits his interests is a challenging one.

The reading interests of adults are greatly influenced by their educational and cultural background. Studies indicate that while nearly every adult reads newspapers, twenty per cent or more do not read magazines, and readers of books are in the minority. Of the books and magazines that are read, a large proportion are light and trashy fiction. Even among college graduates and groups of teachers, the amount of serious and thought-provoking reading is relatively small. The problem of developing lasting interests in worthwhile reading matter is a real challenge for education. (See READING, METHODS OF TEACHING.)

READING, METHODS OF TEACHING. Reading is a highly complex activity, involving a large number of skills that have to be learned. Essentially reading is a process of acquiring meanings from the printed page. For this to be successful, the reader must be able to recognize the printed equivalents of spoken words, to interpret their meanings, and to understand the thoughts expressed in sentences, paragraphs, and larger units. Subordinate to the problem of comprehension, but necessarily important, is the acquisition of delicate and complex eye-movement coordinations for the orderly inspection of printed material. As reading ability develops, the adaptation of basic reading skills to different purposes or motives for reading, and to the requirements set by different types of reading material, brings about a progres-

sive differentiation and refinement of reading habits and skills.

Improvement in reading ability depends upon the ability of the child to learn as well as upon the methods and materials of instruction; maturation is involved as well as learning. In the normal child a steady growth and development of skill in reading takes place as he advances in school. There is, therefore, little justification for abrupt changes in methodology as the child moves from grade to grade. For convenience, however, levels or stages in the instructional process may be distinguished. In the discussion to follow, a brief consideration will be given to the special instructional problems of five stages: preparation for reading, beginning reading, reading in the second and third grades, reading in the elementary grades, and reading in secondary school and college.

Preparation for Reading. Because of the increasing recognition of the importance of reading readiness (*q.v.*), children in most schools do not start formal reading activities at the very beginning of the first grade. The duration of the preparatory or pre-reading period may vary from only two or three weeks to as much as one or two terms for children who seem markedly deficient in phases of reading readiness. In schools with kindergartens, some of the preparatory work can be done before the first grade. Objectives of the preparatory period are detection and correction of physical defects; provision of varied experiences as a background for comprehension; vocabulary development and improved oral English through conversation, story-telling, and dramatization; improvement of perception of similarities and differences, both visual and auditory; development of ability to participate in group activities, pay attention, and follow directions; and arousal of an interest in reading and a desire to read. Some teachers use workbooks upon which reading readiness lessons may be built, while others prefer to develop their own materials.

During the preparatory period a gradual approach to reading is employed. Classroom objects and furniture are labelled. In many schools the children make up little stories about their own experiences, and these are printed by the teacher on the blackboard or

READING, METHODS OF TEACHING

on charts and are used as material for informal reading lessons. The teaching procedure with these charts is usually a story method, and accurate word recognition is expected. The use of experience charts as pre-book material, sometimes referred to as the *Experience Method*, has been criticized because of the likelihood of employing too extensive a vocabulary and providing too little repetition of important words. These are not insurmountable difficulties, and the excellent motivational value of the procedure has caused it to be widely used.

Reading Methods for Beginners. While each set of primary readers has its own variations in method, most of the numerous systems may be classified as belonging to one of a few major types. The *synthetic methods*, including the *Alphabet Method* and *Phonic and Phonetic Methods*, are those in which one starts with word parts and builds up from the parts to the whole; these methods are out of favor as introductory procedures. Methods currently favored are all *analytical methods*, in the sense that in all of them one starts with a meaningful unit—a story, a sentence, or a word—and works down to progressively smaller parts.

Alphabet Method. In the alphabet method of teaching reading, the child was first taught the names of the letters of the alphabet. After these were mastered, two-letter combinations like *ab*, *ac*, and *ad* were spelled and pronounced. The child then progressed to three-letter nonsense syllables, monosyllabic words, and longer words. This procedure, mechanical, uninteresting, and difficult for most children, has long been supplanted by better methods in American schools. It is less suitable in English than in languages in which the letter names and phonetic equivalents are nearly identical.

Phonic and Phonetic Methods. A phonic or phonetic method is one in which skill in word recognition is developed by starting with the sound values of the letters of the alphabet, and teaching the technique of blending or combining them to form words. Strictly speaking, phonetic methods employ a special alphabet or system of diacritical marks to indicate the sound value of each element, while phonic methods do not; this distinction, however, is frequently ignored and the

terms are used interchangeably by many writers.

Phonetic alphabets and diacritical marks have been out of favor for many years in basic reading instruction, largely because of the great variety of English sounds and the complexity of any set of symbols adequate to represent them. Systematic phonic methods have also fallen into disfavor for teaching beginners because they tend to emphasize the mechanics of reading at the expense of comprehension and promote habits of excessive vocalization which later interfere with the development of speed and fluency in silent reading. Phonics (*q.v.*) is generally taught as a supplementary rather than as a basic technique in word recognition.

Word Method. The word method, sometimes called the "look and say" method, is based on the psychologically correct idea that a word is not merely a collection of letters, but has a distinctive appearance and can be recognized and learned as a unit. The usual procedure is for the teacher to put a word on the blackboard, pronounce it, and have the class pronounce it. Obvious distinctive features of specific words may be introduced. After a few words have been introduced, they are combined in short sentences. The introduction of new words with pictures, followed by exercises in which words and pictures are matched, is a frequently used procedure. Added practice of this sort is provided in workbook exercises. Flash cards are commonly employed to develop speed and accuracy in recognition.

The value of flash cards in the development of speed and accuracy in the recognition of words and phrases has been for years a controversial issue. There is experimental evidence that skill acquired in flash card exercises may not carry over to the reading of the same words in connected material. If flash cards are used, this danger can be avoided in large part by following the flash card drill with connected reading containing the same words or phrases. For children whose word recognition is unduly slow, flash card practice is unquestionably helpful. In using flash cards, a cover card should be used, or a simple tachistoscope may be constructed. As with many other specific devices, flash cards have a definite but limited value in reading instruction; when their use is over-

emphasized, the net result may do more harm than good.

The word method makes it possible for a child to develop a reading vocabulary of sight words quickly and begin meaningful reading in a relatively short time. It does not give the child an independent method of attack upon new words and therefore should be supplemented with training in word analysis and phonics.

Sentence Method. The sentence method is based on the assumption that the sentence, rather than the single word, is the natural unit of thought. In a sentence method the teacher usually begins by printing a short sentence on the board or on a chart. The teacher reads it to the class and the class repeats it, individually and in unison. More sentences are introduced. Practice is given in arranging sentences in correct order and in matching sentences with pictures. The same words are re-arranged in different sentences and the separate words are pointed out. From that point on, the method is essentially the same as a word method.

Story Method. The story method starts with the teachers' reading a story, frequently one of a cumulative, repetitive type such as *The Little Red Hen*. In one variation, each sentence is thoroughly drilled in chart and blackboard lessons, so that when the children turn to the story in the book they can already read every sentence. This procedure differs little from a sentence method. In another variation, sometimes referred to as *story-memory method*, the children rehearse the story orally until they know it verbatim; then when they turn to the printed story they are expected to be able to identify each word because they know what word is supposed to come next. This procedure was devised as a means of teaching from primers which contained large vocabularies and introduced new words at a very rapid rate. The development of much easier reading material for beginners has made its elaborate procedure unnecessary.

Non-Oral Method. A program has been developed by McDade in Chicago in which the child is discouraged from engaging in any vocalization during reading. New words are introduced generally by means of pictures or pantomime. Silent reading is compulsory from the beginning. The theoretical

basis of the method is the assumption that oral reading introduces an unnecessary step into the reading process and serves to retard speed of reading. There is not at present enough published research at hand to justify conclusions about the effectiveness of this method as compared with other methods.

Intrinsic Method. In the intrinsic method, the child completes several lessons in a workbook or preparatory book before he starts the first story in a pre-primer. The words of the story are introduced in the preparatory exercises through the use of pictures, matching games, and other devices. It is expected that when the child reaches the story, he should know all the words and be able to read the story with ease. Much reliance is also placed upon context clues. "The setting for each new word should be carefully worked out so that the word is surrounded with such abundant and suggestive context clues that the pupil will be quite sure to figure it out promptly and correctly." Review is provided through comprehension tests which give additional practice on the vocabulary and also check up on the student's understanding of the story. Exercises for accuracy in word recognition emphasize visual discrimination rather than phonics. The method is adaptable to individualized instruction to the extent that the materials are self-teaching. The effectiveness of the whole method depends to a great degree upon the adequacy of the preparatory lessons.

Reading Materials for Beginners. Current first grade reading materials are very much alike, regardless of the specific method for which they are planned. A set of basal readers usually contains from one to three pre-primers, a primer, and a first reader. Correlated with these is a set of workbooks, the use of which is optional. Other optional materials include printed charts or giant books for group lessons and sentence, phrase, and word cards. Pre-primers are thin, paper-covered booklets, most of which are attractively illustrated and contain stories with elements of plot, surprise, and humor, written within the limitations of a much restricted vocabulary. New words are introduced at carefully spaced intervals and with much repetition. The primer, or first hard-cover book; and the first reader, intended for use in the second term of reading

instruction, continue to increase gradually the vocabulary started in the pre-primers. In many series there is a continuity of plot and characters from the first pre-primer through the first reader.

Differences in methodology show up much more clearly in the workbooks and other accessory teaching materials than in the basal readers. The presence or absence of preparatory exercises; the emphasis placed upon picture-sentence matching, picture-word matching, and other teaching devices; the space given to comprehension exercises; and the type of training given in word discrimination and phonics are the major points of differentiation. In nearly all cases some provision is made for beginning training in word analysis and phonics during the first grade—in some systems while the children are reading the primer, in others at the first reader level.

Whether it is better to follow one series through the first reader or to read a number of different kinds of books at each level is a debatable issue. The main argument for the former procedure is the continuity of vocabulary development provided. Those who favor wide reading at each level of difficulty frequently rely upon published studies of overlapping vocabulary to determine the sequence in which several pre-primers or several primers should be read.

Reading in the Second and Third Grades. In the second and third grades, continued systematic attention to the development of basic reading habits and skills is desirable. Training in the techniques of word analysis and phonics is provided to supplement the sight recognition approach usually emphasized in the first grade. By the end of the third grade, the child should be able to work out the pronunciation of most unfamiliar words without help. Oral reading has an important place in the instructional program but by the end of this period it is subordinate to silent reading. The basal reader is the core material for instruction in most schools but is supplemented by a wide variety of easy reading material. In many schools the supplementary reading is centered around units, projects, or activities. The development of a liking for reading and a desire to read independently is a major goal. Because of the extensive use of reading as a

tool of learning in the fourth grade and above, many schools make a concentrated effort in the third grade by means of remedial instruction to bring all the children to the point where they can read and comprehend fourth grade material.

Reading in the Intermediate Grades. By the fourth grade emphasis has shifted in most schools from "learning to read" to "reading to learn." Word recognition skills require less emphasis than before, but some practice in the use of the dictionary and in attacking polysyllabic words is needed. The development of reading vocabulary, both of a general literary kind and of the special vocabularies of the content subjects, is an important problem. Silent reading becomes considerably faster than oral reading and occupies most of the time spent on reading instruction. Training in the use of books and in the location of information in reference works deserves attention. The use of basal readers is continued through the elementary grades in many schools. In other schools, recreational reading is taken care of through extensive, individualized reading; and training in study-type reading is provided in planned sequences of reading lessons based on textbooks in the content subjects, or by the use of study-type readers or workbooks.

Reading in the Secondary School and College. It was formerly taken for granted that those who progressed beyond the elementary grades in the educational system knew how to read, and that no further attention needed to be given to instruction in reading. Many surveys have demonstrated that a large number of students are handicapped in their higher studies by inadequate reading ability, involving either a general marked retardation in reading or an inability to adapt their reading habits to the requirements of a specific subject. At a result, increasing attention is being given to the problems of reading in both secondary schools and colleges.

One manifestation of this interest has been the setting up of remedial reading programs and, in some cases, of remedial reading clinics. These programs, of course, take care only of those students who have recognized deficiencies. Other schools, particularly at the secondary school level, are conducting

experiments in the development of an "all-school reading program" in which every teacher of every subject is expected to be reading-minded, to watch for difficulties in reading, and to teach the special adaptations of reading that his subject requires. This trend is quite new and as yet all of these programs are in an experimental state.

Oral Reading. Years ago instruction in reading was predominantly oral. As greater prominence began to be given to the development of speed and comprehension in silent reading, the emphasis shifted so far in some schools that oral reading was almost entirely neglected above the first grade. The "non-oral" method of teaching beginners eliminates oral reading altogether.

The emphasis upon silent reading has tended to obscure the fact that there are important uses for oral reading, which include conveying information, relaying instructions in exact form, citing authority, and, most frequently, entertaining others. In addition to providing practice directed toward these goals, teachers find use for oral reading to analyze and correct deficiencies in such phases of reading as word recognition, phrasing, fluency, and expression; to improve oral English and use of the voice; and to develop ability to perform before an audience.

Oral lessons should be planned with specific objectives in mind, rather than used as a routine method of having the class read through a story. Useful oral reading procedures include individual reading to the teacher for diagnostic purposes, oral reading of answers to questions based on preceding silent reading, oral reading of carefully rehearsed material in an audience situation, and choral reading of rhythmic material. When one child is reading orally it is usually better for the others to be listening than for them to be reading the material silently.

Reading, Rate of. There is in general a substantial, but not very high, positive correlation between rate of reading and comprehension. While rate and comprehension tend to go together, there are enough cases of high comprehension and low rate, or high rate and low comprehension, to present special remedial problems. No really satisfactory rate norms have ever been established, mainly because the rate at which one reads varies markedly according to one's mind-set

and the difficulty of the material.

Speed is less important than comprehension and should not be emphasized until a thorough basis for good comprehension has been established. If there are deficiencies in word recognition skills, phrase reading, or comprehension of sentences or paragraphs, these should be attacked first. If comprehension is poor because of excessive speed, the individual should be informed that he is reading too quickly; frequent and thorough questioning should be used to check his understanding. When comprehension is adequate, the following simple program is usually satisfactory for improving rate of reading: (1) make the individual aware of the desirability of reading faster; (2) see that he reads a large amount of easy, interesting material; (3) measure rate and comprehension on similar material at frequent and regular intervals; (4) have the individual keep a graphic record of his own rate and comprehension scores; (5) set reasonable goals so as to prevent unreasonable hopes and consequent discouragement; and (6) since automatic transfer of training cannot be assumed, utilize varied types of practice materials. (See PHONICS; READING DISABILITY; READING, EXTENSIVE; READING, RECREATIONAL; READING VOCABULARY; STUDY; WORD ANALYSIS.) A.J.H.

READING READINESS. The degree to which a child is capable of profiting from beginning instruction in reading is called his reading readiness. Lack of reading readiness may result from any of a number of deficiencies: the child may be normal for his age but too young for reading instruction; he may be generally slow in mental development; he may have a very narrow and limited range of experience because of

a restricted environment; his understanding and use of English may be deficient because of a foreign language background, excessive use of baby talk, or other reasons; he may have defective visual or auditory acuity; he may have poor perception for similarities and differences in word sounds or in visual symbols; he may be unable to adjust to a group situation, to follow directions, or to pay continuous attention; he may be emotionally unstable, extremely timid, or otherwise unable to make a satisfactory adjustment to the learning situation. Typically a child is deficient in readiness for reading is handicapped in several respects, not just in one.

Success or failure in school depends upon the rate of progress demanded, the methods and materials used, and the amount of individual assistance given, as well as upon the abilities of the child. It follows that no uniform standards can be established as minimum requirements for beginning reading instruction. In general, however, children who are at least six years old, of at least average intelligence, and not seriously handicapped usually make satisfactory progress in the first grade. The others are less likely to fail if their handicaps are investigated and corrected so far as is possible, and if they are introduced to reading at a rate considerably slower than that of a conventional first-grade program.

In selecting children who are likely to have difficulty in learning how to read, ratings by the kindergarten teacher, intelligence tests, and reading readiness tests are helpful. Reading readiness tests are tests suitable for use with kindergarten and first grade children, which measure aspects of intelligence and acquired knowledge that are important in reading.

It is recognized that the concept of readiness applies at higher levels of reading as well as at the beginning. As yet, however, little progress has been made in determining or measuring the essential criteria of readiness above the beginning level. (See *READING, METHODS OF TEACHING.*) A.J.H.

READING, RECREATIONAL. Recreational reading is reading which is done pri-

marily for personal enjoyment, with gains in knowledge or understanding of secondary importance. In the teaching of reading, recreational reading should be clearly distinguished from work-type reading or study. Each should have its own objectives and methods keyed to those objectives.

In recreational reading the teacher's main purpose is usually to follow and enjoy the plot of a story. Other motives may be to enjoy humor, to appreciate beauty of expression or excellence of description, or to view the world through the author's eyes. Important abilities that are required are facility in getting the general idea of a selection, ability to follow a related sequence of events, and understanding of the motives and emotional reactions of the characters.

Instruction in recreational reading which carries detailed analysis to the point where interest and enjoyment decrease, defeats its own major purpose. This is the central theme of many changes in the handling of recreational reading in the schools. It has shown itself in the following ways: (1) There has been a marked decrease in the "intensive study of the masterpiece." (2) The classics have lost ground to contemporary materials which have greater interest appeal. (3) The type of basal reader emphasizing literary selections has decreased in popularity. (4) There has been a marked increase in the use of various plans for individualized extensive recreational reading, for which the term *Free Reading* has been adopted. (See *READING, EXTENSIVE; READING, METHODS OF TEACHING; STUDY.*) A.J.H.

READING, REFERENCE—See *STUDY*.

READING, REMEDIAL—See *READING DISABILITY*.

READING VOCABULARY. The teaching of reading vocabulary has two aspects: the acquisition of ability to recognize or work out the pronunciation of a word, and the learning of concepts and word meanings. In the primary grades most new words that the child meets in reading are already familiar in meaning; the problem is one of discovering the pronunciation of the word. In the middle grades and above, the major vocabulary problem is the acquisition of meanings.

Many children acquire new word meanings

effortlessly and naturally by guessing at the meaning of a word from the sense or context of the sentence in which it is contained. If the child is skillful at this kind of guessing and reads widely, he will develop a wide and rich general vocabulary with little or no specific teaching. Poor readers who are not adept at guessing from the context and who do little voluntary reading cannot be expected to gain an adequate reading vocabulary in this way.

The conventional procedure of preceding the actual reading of a new selection by preliminary teaching of the new concepts and vocabulary is satisfactory in most teaching situations, provided that only a few essential words are taught at one time and that the meaning of each word is adequately developed. Incidental vocabulary teaching in which the pupils are expected to ask about unfamiliar words is more successful with good readers than with poor ones. If the number of essential new words is greater than the pupils can learn, the problem is primarily one of securing easier reading matter. This problem is particularly acute in the teaching of content subjects, where it is frequently difficult to get textbooks with a reasonable vocabulary load.

Teaching the use of the dictionary is an important phase of vocabulary instruction in the elementary grades. Most children benefit from specific lessons to develop speed and accuracy in the location of words in alphabetical order and in the interpretation of dictionary definitions. Motivation to use the dictionary is usually necessary; a vocabulary notebook or pack of individual word cards is helpful. Practice in finding synonyms, antonyms, homonyms, and in classifying words according to different kinds of relationships is of assistance in developing greater flexibility of vocabulary and greater precision of understanding.

There are available a number of vocabulary lists, representing the results of word counts totaling millions of words. These lists have been extensively used by the writers of books for children. They have been very helpful in encouraging the simplification of vocabulary in children's books and in bringing about a greater agreement on the words that should form the core vocabulary of basal readers and other school books. Among the

most widely used vocabulary lists are those by Thorndike, Gates, Horn, Buckingham and Dolch, Stone, and Durrell, and the technical vocabulary lists by Cole. (See **READING, METHODS OF TEACHING; VOCABULARY ENRICHMENT.**)

READING, WORK-TYPE—See STUDY.

REALIA. The use of actual objects, or *realia*, in the classroom has accompanied the move toward more concrete teaching. Realia help the pupils form a correct initial concept of the thing being taught.

The term is used most frequently in foreign language teaching and refers to materials of foreign origin—newspapers and magazines, travel posters, theatre and railway tickets, folk costumes, photographs, records, films, games, music, etc., as used in the classroom to make the instruction more lively, more real, and more interesting. As the social aspect of foreign language teaching is being emphasized more and more in integration with the linguistic aspect, the selection and the use of culturally significant materials are becoming a major concern of foreign language teachers. This concern is reflected in new courses of study evolved in recent years in Denver, in New York City, at the University of Chicago, and in the Stanford Language Arts Investigation. (See **AUDIO-VISUAL AIDS; AUDITORY AIDS; FOREIGN LANGUAGES, TEACHING OF.**)

REALISM. There is both a practical and a philosophical sense in which realism has been important in education. On the practical side realism usually comes into prominence when education has had a tendency to become overly abstract, bookish, or verbal. At such times the cry to make education more realistic usually means to give the concrete

and practical aspects of life a more central place in the learning process.

Historically and currently this sort of realism has taken three forms in the curriculum. First is humanistic realism. Here the curriculum remains literary but it is selected and taught with the current needs of society prominently in mind. Second is social realism. Here the curriculum does not discard literary studies but subordinates them to what can be learned first hand through direct social contact. To avoid narrowness this sort of education almost inescapably demands wide travel. Because it does, it is generally limited to the upper classes since only they are able to afford it. Third, and perhaps most important, is sense realism. The reality emphasized here is the physical world of fact known through the senses. Here the curriculum is made up largely of the sciences. In Germany a school with such emphasis was called a *realschule*. Furthermore, sense perception plays a large part in the learning process: witness the *Orbis Pictus* of Comenius (*q.v.*) and the object instruction of Petalozzi (*q.v.*).

From the philosophical side the resort to realism is usually an endeavor to found educational theory and practice on the most secure metaphysical base possible. The basic question here is, what is the truly real? The answer to this question is not unrelated to the foregoing contrast between the abstract and the concrete. In the nominalist-realist controversy, which occupied the forestage of medieval schools, it was the nominalists, not the realists, who claimed that reality was to be identified with the concrete and the particular. The realists of that period, on the other hand, contended that reality in its most durable form was to be found, not in the concrete and particular, but in the abstract and the universal. Since the former had so many "accidental" qualities subject to changes of time and place, it seemed obviously best to the realists to predicate education on those universal concepts which could be stated as true for all men in all times and in all places.

The same problem has also presented itself in epistemological form. Because idealists and pragmatists have been strongly guided by the usefulness of pupil's ideas and purposes, anxiety has arisen that education

would become so subjective as to lack any vertebrate character. Critics, calling themselves realists, have therefore come forward asserting that there is a world of concrete objective reality *independent* of the child's or teacher's mind and will to which education must conform if it is to be successful.

This account of realism would not be complete without a word about the part it played in Herbart's educational psychology. On the one hand Herbart (*q.v.*) posited that the world was composed of a plurality of "reals" and on the other that the individual's basic equipment to come in contact with these "reals" was not faculties but a rather colorless soul. Consequently, the individual developed, not according to some inner law, but by reacting to "reals" as they were "presented" to him from without. Earlier reactions were thought to persist as ideas and thus to influence through "apperception" later presentations.

RECALL TEST — See **OBJECTIVE TESTS AND EXAMINATIONS**.

RECAPITULATION. The theory of recapitulation holds that there is a parallelism between individual and societal development so that at each stage of his development the child should study the culture of the corresponding epoch of societal evolution. By arranging the curriculum in a series of "culture epochs" the child would, in the course of his education, recapitulate the history of mankind. (See **CULTURE EPOCH THEORY**.)

Although the theory was popularized by the Herbartians (See **HERBART**), it was by no means original with them. Their interest in the theory grew largely out of the use they were able to make of it in the development of another theory, the theory of correlation. This theory called for the grouping of subjects so that their mutual similarities would facilitate learning through "appercep-

tion". This led to an attempt to "concentrate" the curriculum about a central core for each grade. But what should the different cores be and in what order should they be presented? The theory of recapitulation or culture epochs suggested a ready plan.

Some thought there were three, some five, and some even eight different epochs. Some made their divisions according to sociological, some according to psychological, and others according to economic principles. One of the most notable was that which marked the following divisions: (a) savage (b) nomadic (c) agricultural (d) domestic handicraft (e) industrial. Accordingly, there is a period when the child is a little savage and, however inconvenient, one through which he just must pass. During this period he will probably have an interest in hunting and fishing and stories like *Robinson Crusoe*. Similar illustrations can be made for other epochs.

The assumed soundness of this theory has been rested on various other disciplines. In the first place it has drawn strength from a philosophy of history. Whereas both rationalism and naturalism (*qq.v.*) had been individualistic and had attempted to shelve the old culture in favor of a fresh start, a new school of thought sprang up to emphasize the importance of the continuity of culture and the role the long past plays in bringing the individual to his present stage of development. From this it was but a step to state more explicitly the stages through which the individual passed in order to achieve self-realization. In the second place, when the theory of biological evolution appeared, this philosophy of history seemed to have scientific reinforcement. Finally, even greater scientific support seemed to attach to the theory of recapitulation with the discovery in embryology that the embryo in its gestatory period (ontogenesis) recapitulates the evolution of its species (phylogenesis).

Various criticisms have been levelled against the theory of recapitulation. Against its scientific support it has been pointed out that ontogenesis does not completely repeat phylogenesis. On the contrary, nature seems to make short cuts. Similarly, against its pedagogy it is stated to be wasteful, to say nothing of enormously time consuming, for a child to have to repeat the whole past of his race. Furthermore, there is the constant

educational danger of subordinating the present to the past just because it is the past.

RECESS. The school program for the pupils of the elementary school, especially in the lower grades, is often arranged to provide the children with at least two recreational or recess periods during the school day. The periods are generally set about midway between the opening of the school day and the noon lunch period, and midway between the lunch period and dismissal in the afternoon.

The purpose of the recess period is to give the pupils a chance to get physical exercise, or play activities, that will tend to bring about relaxation.

The length of the recess period varies somewhat in different schools and often in the different grade levels within a single school. Usually, the period of relaxation is longer for children in the primary grades than for the children in the intermediate and upper elementary grades. The period range is from ten to twenty minutes in most schools.

In the more progressive schools the formal set period known as "recess" has been abolished. The daily program for the pupil is a balanced one including rest, recreation and work. Each activity is followed when the needs of the children indicate it is necessary.
O.G.J.

RECIPROCAL CERTIFICATION — See CERTIFICATION OF TEACHERS.

RECITATION. The various interpretations of the term *recitation* have often led to considerable confusion among teachers over the application of the term. According to its etymology the term means re-citation of a learned lesson. Apparently the original application was just that—pupils re-cited to the teacher what had been studied previously, and the lesson period thus also became known as the recitation period, or simply the recitation. David Page in his *Theory and Practice of Teaching* (1847) used the term *recitation* synonymously with "reciting a lesson." The emphasis upon reciting led many teachers to use the recitation only for

RECITATION

that purpose, although good teachers in early days looked upon the recitation as a lesson period during which other activities, as well, were carried on.

With the spread of the Herbartian influence in this country (1860-1900) the term recitation was applied to the lesson period as a period of planned procedure under the teacher's direction. Here was the beginning of planning lessons as lesson-units. The McMurrys' *Method of the Recitation* (1897) set forth general methods of procedure to be used for lessons as learning-wholes, with the idea that such lessons might take more than one recitation period. It was the beginning of more flexibility in conducting recitations and also emphasized the idea of using the kinds of learning experience pupils needed to acquire desired outcomes. Type procedures, however, were stressed.

In consequence of these influences, teachers conceived the idea of planning lessons according to recitation patterns, which gave rise to the drill lesson, the inductive lesson, the deductive lesson, the appreciation lesson, etc., with emphasis upon certain types of experience. This was an attempt to improve classroom work by choosing and planning the learning experiences for certain ends. In his book *A Brief Course in the Teaching Process* (1911), Strayer included among other lesson types the "recitation lesson." The recitation advocated by Strayer was a distinct improvement over the older type of recitation, yet it embodied the concept of a lesson to be recited. In *The Recitation* (1911) Betts referred to the recitation as the "teachers' point of contact with his pupils" and stated that the three purposes of the recitation are testing, teaching, and drilling. He suggested different methods of securing pupil activity, such as the question-and-answer method, the topical method, the lecture method, and the written recitation. These illustrations show that the recitation still was thought of as a period for reciting or going over an assigned lesson.

From 1910 to 1920 several influences helped to bring about further changes in the methods of teaching and organizing classroom activities. Among these were (1) the increased emphasis upon individual differences and the ways of making suitable provision for variations in ability and interests,

(2) the recognition of the importance of the social setting as a factor in learning, (3) the stress placed on pupil purposing and pupil participation in planning and directing their own learning activities, and (4) the trend toward planning classroom activities in larger learning-wholes. The gradual influence of these ideas resulted in several radical departures from the traditional recitation type of procedure. Among these were the Dalton Plan (1919), the Winnetka Technique (1919), and the Morrison Unit Technique (1919) (*qq.v.*). There was at the same time renewed emphasis upon the project and problem-solving procedures (*qq.v.*). The use of the unit as a plan for organizing both subject matter and pupil experience and the use of the differentiated unit assignment to provide for individual difference can be traced to this period.

In spite of these influences many schools, both on the secondary and elementary levels, continued to use the traditional recitation technique with emphasis upon the topical and the question-and-answer methods of development. Because this traditional use of the recitation did not provide satisfactorily for pupil participation, many teachers tried making other provision for such activities. This gave rise to the so-called contribution or socialized recitation (*q.v.*). In general two types of the socialized recitation, the formal and the informal, have been used. The former designates a type of classroom organization in which the class is organized in imitation of some adult group, such as a city council, in order to study that organization and its work. The informal type includes all other socialized recitations in which the pupils participate in various ways in planning and carrying out the work of the class under the teacher's supervision.

Following the early 20's there was a rapid growth in the use of the unit both in curriculum construction and in the organization of classroom activities. The unit emphasized planning larger learning-units and making the daily classwork a series of successive steps in the development of the larger whole. The use of the longer unit and its emphasis upon learning experiences to fit the learning situation tended to bring into wider use a variety of procedures such as the discussion procedure, the developmental procedure,

practice activities, drill, lecturing and telling, lecture-demonstration, review, supervised study, etc. (*q.v.*). Teachers also made effective use of various pupil activities that belong to no particular type of procedure yet are essential learning experiences, including dramatization (*q.v.*), pupil reports, debates (*q.v.*), panel discussions (*q.v.*), pupil demonstrations, field trips (*q.v.*), etc.

In spite of the new emphasis upon longer units and the adaptation of learning experiences to fit the learning situation, investigations indicate that the majority of teachers of content subjects in both the elementary and the secondary schools are still thinking in terms of lessons to be studied, although the recitation as a pattern of procedure appears to be going out of use. However, a growing number of teachers are thinking in terms of the many kinds of essential pupil activities instead of types of lessons. Since the emphasis is increasingly upon practical learning experiences, the tendency is to drop the use of the term recitation except to indicate a period of classwork. T.M.R.

RECONSTRUCTION OF EXPERIENCE. The term was introduced by Dewey (*q.v.*) in his discussion of education as reconstruction of experience. To quote the definition in *Democracy and Education* (pp. 89 ff.), education "is that reconstruction or reorganization of experience which adds to the meaning of experience, and which increases ability to direct the course of subsequent experience." What Dewey wished to call to attention is the fact that in any act of learning the learner is to some extent remade; he faces his next experience as a different person; he brings to it a new increment of

sensitivities, insight, feelings, habits which cause him to meet it as he would not before have done. The young child snapped at by a dog now sees a dog as something to be approached with caution—he sees new meanings in the dog; he can control his next experience with dogs more intelligently. He is thus remade; his experience has been reconstructed.

Recent psychological study definitely reinforces Dewey's conception and extends it. It is increasingly accepted that learning is not a mere process of accretion but is instead pervasive, reaching into all aspects of the organism. The organism learns as a whole. The child above is affected in his glandular reactions, his emotional responses, his understandings (of dogs, of what it means to be in a tight place), his physical skills (running, perhaps, or wielding a stick). But still further: the newer psychology is discussing reconstruction of experience when it stresses the fact that each instance of learning penetrates into all related past learnings and so entails, to greater or less extent, a reorganization of the organism's patterns, a new integration of his outlook and abilities and tendencies to behavior. Each instance of learning is thus continuous with and grows out of the learner's previous response patterns, but the process is not merely one of addition or summation. Old patterns must be remade to include the new. The child revises his relationship with dogs and also his relationships with other animals and with the human beings to whom he looks for security in a crisis; his quiver of fears is enlarged; his preferences change as to parts of town to visit hereafter; his outlook on life is accordingly modified.

Acceptance of this conception tends to carry with it acceptance of various implications: (1) that "learning" which does not affect subsequent living is of slight importance. Learning which is chiefly verbalization is accordingly discounted. For though ability to repeat a rule of grammar does in a sense change the child's approach to life, true reconstruction of his experience in this respect would be measured by his tendency to take account of the grammar in his ordinary speech. (2) stress on learning through meaningful experiences which the child can take active part in developing and through which

he can be helped to remake his behavior patterns fruitfully (e.g. learning science through working to improve community health, in contrast to learning chiefly from books). (3) recognition of the pervasiveness of learning inclines educators increasingly to include in their purview provision for the various types of responses being made by the child—emotional responses, attitudes, and outlook being formed, personality effects, physical effects, as well as the academic content. RECORDS AND REPORTS. Records and reports have a close and intimate relation. In general the report becomes the vehicle for conveying information contained in the record. This relationship is well illustrated in records kept and in reports made by teachers relative to their pupils. Records of attendance, enrollment, and scholarship become the basis for making the teacher's monthly and annual reports to the principal or superintendent.

Records and reports may deal with pupils, teachers, other personnel, school property, or school finance. They may differ in that records tend to be permanent and reports temporary; records tend to be made by an individual or by an office for his or its own use whereas the report is made for the use of some other individual or office; records dealing with personnel tend to be individual while reports usually represent summary statements regarding groups of persons. These differences are not always clear cut; the "report to parents," for example, is individual.

Pupil accounting has many types of pupil records such as the school census record, the teacher's school register or class book, the principal's office record, and the pupil's cumulative record; these records are sometimes classified and constructed as physical records, standard test records, scholarship records, and the like. Reports to principals, superintendents, and the state and federal

offices are based upon the data contained in such records.

Records and reports are essential if a school system is to be managed for effective service to the pupils and at the same time without waste. Administrative officers of a school system need to know where and how school monies have been expended; they need to know what has happened to school equipment and supplies; and they need to know how effectively the hired personnel of the school system are performing. Unless records are kept and reports assembled, they do not have a clear picture of what is happening within their systems.

Administrative officers, principals, and teachers need to know the abilities, capacities, interests, and attitudes of the pupils they are trying to serve; they need also to know what progress these pupils are making while they are under the school's supervision. The only method of making sure that such data are available and usable is by the keeping of accurate records and the making of regular reports.

School records and reports to be effective must be developed in terms of specific purposes; if a given record aims at measuring pupil progress, all data that have no bearing upon this problem can be eliminated unless at the same time this record is to serve other purposes. Such a careful analysis in terms of purposes will avoid the assembling of unneeded data; at the same time, it will guarantee the providing of other numerous data that are often ignored and that are essential to an adequate appraisal of pupil progress.

School records must be continuous and cumulative. Such records give an opportunity to compare achievement from year to year; they portray the growth of pupils, teachers, and other employed personnel; and they provide accurate data about the schools at any given date during the year.

Office Record Card. An office record card may be the record card maintained by the superintendent's office concerning his teachers, pupils, other employees, or material; or it may be the pupil record card maintained by the school principal's office. Of these, the principal's office record card is perhaps the more common; this card appears in various forms and sizes. A 4" by 6" card, filed in packets that permit the insertion of several cards, is used in Baltimore; many

RECORDS AND REPORTS

sizes are in use but the 5" by 8" and 8½" by 11" are the most common.

In place of a card, some school principals use sheets that fold and fit 5" by 8" card files; others use sheets 8½ by 11 inches on heavy bond paper; some use folders with items of information about pupils typed upon the folders; and still others use a manila folder with only the pupil's name typed upon it, into which are placed all kinds of cards, sheets, letters, and other materials about the pupil. This record provides permanent data concerning given pupils; it never leaves the school. If a child is enrolled in a given school for only 6 weeks, this record tells the facts concerning the pupil's school experiences during those 6 weeks. If a child attends 12 different schools during his 12 years in the public schools, there will be 12 principal's office records made out for him.

Such a record protects the pupils against loss of credit for work done in the school; this is its primary function. It may serve in small schools as the pupils' cumulative record as well as an office record; in such cases it is most useful in the school's guidance program. It enables the principal to inform himself quickly about given pupils who for various reasons may be called to his attention; this puts him in the position of answering quickly the many questions that flow constantly through his office relative to his pupils. It may become the basis for knowing the name, the family background, and past school success of each of his pupils; such knowledge may well be the means of decreasing disciplinary problems, adjusting the school's program to meet better the needs of its pupils, and improving school morale.

Cumulative Record Card. The cumulative record card is a recent addition to pupil records. Strictly speaking any pupil record card that is maintained permanently and has data added to it constantly so that all its information is correct as of any date is a cumulative card. In this sense, the modern continuous school census cards are cumulative, for such new data are added and old data are changed as is necessary to give us as correct a picture of the child as possible; the principal's office record is also, in this sense, a cumulative record.

The cumulative record card is beginning,

however, to take on a more restricted meaning; in this newer sense, it means a record card that follows the pupil, not only from school to school, but from teacher to teacher. Each new teacher adds to the record upon the basis of her contact with the pupil.

In non-departmental elementary schools, this means that each teacher has such a record card for each of the pupils in her class; she is responsible for keeping the record safely, adding pertinent data to it, bringing old data up-to-date, and passing it on to the pupil's next teacher. In departmental elementary schools, this record card is kept, used, and maintained by the homeroom teacher who passes it on to the pupil's next homeroom teacher. In secondary schools, this record is kept, used, and maintained by those teachers or administrative officials who are responsible for guidance; if the homeroom has been organized as the basic unit in the school's guidance program, then the homeroom teachers keep, use, and maintain this record card.

Present data seem to indicate that in 1908 Charles Lamprey, Principal of the Model School in Boston, was the first person to devise and use such a record card. He called it the "admission, discharge, and promotion card." It contained only a minimum amount of data. Similar forms were made a part of several commercial systems of pupil record forms during the next two or three decades. A more extensive record of this type was published in 1929; this took the form of a sheet to be used in a teacher's loose-leaf register; forms were prepared for both elementary and secondary schools; these forms were to follow the pupil from teacher to teacher and from school to school; they provided far more data about the pupil than did previous forms. Baltimore uses a "packet system" of 4" by 6" cards in place of the single card or the sheet; the State of Michigan uses a sheet that folds into a 5" by 8" folder as its pupils' cumulative record. Duplicates of cumulative records may be and often are used as the principal's office record as well.

Such a cumulative record permits the classroom teachers, the homeroom teachers, or the school officials responsible for guidance to have at hand complete data concerning their pupils. A third grade teacher, for example, would have on the opening day of school, or even several days before, information about the home life, play life, and school

life of every pupil in her class. She would have a report on the pupil's abilities, aptitudes, interests, and habits; she would be better able to work with her pupils in developing materials that would best meet their needs; she would not need to go to the office record card for specific data about her pupils; and she would be saved the task of re-collecting pupil data that previous teachers had already collected.

Reports to Parents. Reports to parents are statements that the public schools send periodically to parents showing how their children are progressing in their school work. These reports tend more and more to be based upon the pupil records that teachers keep. Originally these reports merely informed the parents of the "grades" made by their children. Later, there were added to this purpose certain other goals. The teacher was to be protected from undue criticism for failing pupils without informing the parents of the child's deficiency. The pupil was to be stimulated to do better work by knowing his "grades" and by knowing that his parents also knew them.

The preceding objectives are still dominating goals governing most reports sent to parents. Some educators, however, see other and, they believe, greater values attached to such periodic reporting. They believe that the report should be a means of bringing the home and the school into closer relations; they maintain that most criticisms that parents make concerning the schools are the result of misunderstandings and that these reports, carefully and adequately made, can be so informative that these misunderstandings can be largely eliminated. Secondly, educators see these reports as a means of stimulating pupil growth; they claim that, if the reports are properly made, pupils can turn to them for information about specific weaknesses as well as about specific strong points; they also claim that if these reports are properly managed teachers and pupils will be brought together in the task of diagnosing pupil abilities and in the work involved in interpreting these diagnoses. This pupil activity in connection with the making and using of these reports, it is insisted, makes possible real pupil growth. (See *ANEC-DOTAL BEHAVIOR JOURNAL*.)

The method of making these reports to

parents varies all the way from the use of a small card reporting just "grades" to the writing of a somewhat extended letter that describes in some detail the strengths and weaknesses of the student and that omits entirely the typical formal "grades." Current practice leans heavily in the direction of "grades" that are reported upon small formal cards. These "grades" are stated in terms of letters *A*, *B*, *C*, *D*, and *E*, or *F* where *E* or *F* represents failure. When one is familiar with the variability of "teacher marks" or "grades," the inadequacy of such reporting is apparent. A "grade" of *B*, for example, may be given by teacher *X* to the best pupil in his class and by teacher *Z* to the poorest pupil in his class; it is quite possible, moreover, that the pupil in *X*'s class might be the ablest pupil in the entire school and the one in *Z*'s class might be the poorest. Deficiencies in this method of reporting became apparent with the realization that, even if the grade *B* were properly given there is available no information as to why the pupil got a *B* instead of an *A* or why he got a *B* instead of a *C*. (See *STANDARDS OF ACHIEVEMENT*.)

Many school systems are attempting to correct some of these deficiencies by rating the pupil on effort, study habits, and various character traits; these additional "grades" give some general notion as to the causes of low or high grades. Other school systems make an analysis of the goals to be achieved in given courses as well as of the general goals being striven for by the school; the pupil then is rated or checked as satisfactory or unsatisfactory upon each, or upon as many of these goals as the teacher feels capable of rating. Other school systems write letters to parents when the pupils are in danger of failing and urge a conference; some write letters to the parents of pupils who are doing unusually good work as well as to the parents of pupils who are failing. These school systems retain the regular periodic report card as a part of their reporting procedure.

A few public schools are experimenting with the writing of letters and have abandoned the formal report card; these school systems are usually small. They usually plan a program for informing parents of the change and for giving the reasons for making this change. The so-called progressive schools

RECREATION

have led the way in the use of this type of report to parents.

Some of the problems faced in making this letter type of report are (1) providing the data necessary for writing such an intimate and detailed story of the pupil's progress; (2) avoiding stereotyped phrases and letters; (3) satisfying parents who are accustomed to thinking in terms of ratings of *A*, *B*, and *C*; (4) finding time to become well enough acquainted with the 30 to 40 pupils in each of 4 to 6 classes in a large public high school to write an informative letter about the pupil; and (5) finding the time to write these letters about each of these pupils.

Current tendencies in reporting to parents seem to be (1) less frequent reporting for all pupils; (2) more frequent reporting in cases of exceptionally good or exceptionally poor performances; (3) ratings on many more traits and abilities than formerly; (4) making the reports more and more descriptive; and (5) reporting data for the purpose of furthering pupil growth. RECREATION. Recreation includes all activities that are satisfying and are engaged in for their own sake. In recreation the individual finds opportunity for self-expression, and from it he derives relaxation or enjoyment. Although he sometimes finds these also in his work, recreation is confined normally to leisure time. Because it affords outlets for the expression of personality and yields fundamental satisfactions, recreation needs little further justification; yet physical and mental health, good citizenship, safety, character, and neighborliness are its common by-products.

Because people often gain satisfying experiences from the same kinds of activity, the activities have come to be considered as forms of recreation. Essentially, however, recreation is the attitude characterizing participation in these activities.

Activities commonly considered as recreation may be grouped under several categories, each representing a major type of interest: active games and sports (low-organized games, athletics, and team games and sports); social activities (banquets, card games, parties, and socials); music activities (singing and instrumental playing, whether participated in or listened to); arts and crafts (a wide variety of activities using various media); theatre activities (varying from the presentation of informal dramatizations to the production of full-length plays and community pageants); dancing in its various forms; nature and outing activities (camping, excursions, gardening, and nature study); mental and linguistic activities (discussion clubs, creative writing, reading, and mental games); collecting and other hobbies; and service activities in connection with club, school, church, or playground.

Recreational activities cover the whole field of human interests. The forms in which people engage vary as widely as the interests of a single individual vary throughout his lifetime and as the interests of different people vary one from another. Beginning with the doll play of babyhood and continuing through the active games and sports of youth to the quiet pastimes of old age, the variety

of activities in which a person may engage for relaxation and pleasure is almost limitless. Yet in comparison with the difference in the recreation interests of a group of people, this diversity of an individual's interests is small.

The provision of recreational opportunities for all has become a matter of public concern. Recreational facilities and leadership are now provided at all levels by private organizations, by governmental agencies, and by commercial concerns. Schools, churches, and other social agencies are giving increasing attention to recreational activities. The neighborhood playground and the playfield are most essential because they serve the day-by-day needs of the people. Their usefulness is enhanced when they also provide indoor facilities, thus affording a combined indoor-outdoor recreation center. Often school grounds are developed as playgrounds or playfields, and school buildings commonly are opened for recreation use by community groups.

Competent leadership is as essential in the recreation program as in schoolwork. The chief purposes of play leadership of children are to fill the child's play hours with varied, attractive, creative activities, which foster the free expression of his play interests, and to conduct these activities so that every child is assured a happy and satisfying playtime. The chief function of recreation leadership for young people and adults is to draw out, strengthen, and put into action the leadership capacities inherent in members of the group. Through the widespread adoption of standards of experience and training for recreation positions and the establishment by colleges and universities of courses in recreation methods, activities, and administration, recreation leadership has progressed far on its way toward the attainment of professional status.

REFORMATORY SCHOOL. In almost any reformatory an educational program exists in name if not in fact. The educational offering in the reformatories of this country vary from practically nothing to well organized, comprehensive, and purposeful programs. The programs of excellence are comparatively rare. Programs of average quality are more numerous but those of less than average or of very poor quality predominate.

Obstacles which have retarded the development of reformatory educational programs include the following: inadequate knowledge of the educational process by administrative officials; institutional staffs selected through political patronage rather than for fitness; the traditional lack of interest and antagonism of the public toward offenders against the law; lack of financial resources and unenlightened penology. Reformatories for juveniles and young adults accept the educational process as an essential part of their programs much more readily than do prisons. However the majority of such institutions adhere closely to the outmoded patterns of the traditional public school. Nevertheless, reformatory programs are likely to be much poorer than public school programs.

Too often such institutions are truly the crime schools of fact as well as of fiction. It is believed by some who have studied the problem, that the reformatory system of the present day, which has changed little since its inception seventy-five years ago, is wholly inadequate for the purpose it is intended to serve. Comparatively, reformatories as a whole include better programs in all respects than do prisons. The kind of educational program envisioned in modern penology is more likely to be found in reformatories than in prisons for adults. All reformatories stress

REGENTS EXAMINATIONS

vocational education but very few of them give thought to the purposeful education of the whole individual. There is too much adherence to education in the formula form, and not enough effort to change antisocial or unsocial attitudes and habits of action. In many programs little if any attention is given to educational processes aimed toward the creation of a desire to change an unacceptable attitude—no thought of capitalizing individual social assets and eradication of liabilities.

The term "reform school" is usually applied to reformatories for juveniles. The educational programs in such institutions, while usually inferior to elementary school programs, aim to parallel them. Reform schools for juveniles usually contain nearly all of the defects of the reformatory for young adults and in addition some others characteristic of themselves. (See CORRECTIONAL EDUCATION, PRISON SCHOOL.)

W.M.W.

REGENTS EXAMINATIONS. The general control of public education in New York State is vested in the University of the State of New York, an administrative and supervisory body rather than a teaching institution, governed by a Board of Regents elected by the State Legislature. One of the principal ways of exercising supervisory control over the schools is by means of an extensive program of examinations, popularly known as the Regents Examinations. As early as 1865 preliminary examinations were inaugurated to provide a uniform standard of scholarship for admission to secondary schools. In 1878 a system of advanced examinations was established to serve a similar function for secondary school graduation and for college entrance. In recent years relatively less attention has been given to the enforcement of uniform standards and much more emphasis has been placed upon the diagnostic and guidance function of these examinations.

A State Examinations Board, consisting of five representatives of the colleges of the state, five school superintendents, five high school principals, and five ex-officio members of the State Department of Education constitute an advisory council to the Board of Regents on examinations. The actual preparation of the examinations to be used in

January and June of each year is by committees appointed by the council because of their special competence for this work. Each committee usually consists of one college representative, two or more high school representatives, and the State supervisor in that field. Each committee prepares tentative drafts of the examinations in its field from preliminary copies submitted by the individual members. These tentative drafts of the examinations are then submitted to the State Department of Education where they are subjected to critical editing and revision. Later these revised examinations come before a revision committee appointed by the State Examinations Board for final revision and approval. The objective questions are likely also to be given a preliminary try-out and the results analyzed statistically to determine whether they are of appropriate difficulty and whether they discriminate properly between good and poor pupils.

In spite of the fact that no pains have been spared to make the Regents Examinations a truly co-operative and democratic enterprise, many educators in the state, particularly in New York City, have in recent years become increasingly critical of these examinations. One serious indictment is that teachers often allow the passing of the Regents Examinations to overshadow other objectives of instruction and that in general these examinations tend to exert an unwholesome inhibiting effect upon local initiative. Teachers have objected, too, to the exaggerated emphasis focused upon the examinations and to the importance attached to coaching pupils to pass. School administrators are easily tempted into making the error of regarding the percentage of pupils passing as a convenient measure of the teacher's efficiency. This modified form of "payment by results" further restricts the teacher's influence over the selection of subject matter and inhibits more frequently than it should the teacher's readiness to explore new teaching and learning procedures. It is probable, however, that any injurious effects of the New York Regents Examinations are the inevitable accompaniment of any system of uniform examinations, no matter how they are prepared or administered. At any rate, the extent to which any impersonal system of supervision can take the place of direct personal contact with the

schools must still be regarded as a debatable question. C.C.R.

REGISTRAR. The registrar in public schools and colleges is the officer responsible for the keeping of records and grades, supervision of admissions, registrations, class and room schedules, and pupil and teacher programming. In addition he has many other functions, including guidance and research. In some institutions, especially colleges and universities, he assists in the planning of curricular and educational policies. In the public schools the principal is usually responsible for registration. Frequently he is assisted by clerks and teachers trained for the work. In colleges the common practice is for a full-time officer to be employed as registrar or director of admissions. The duties of the registrar are more complex on the higher than on the elementary level of education because of the increased need for individual guidance and the greater choice of courses and subjects. REGRESSION (PSYCHOLOGY). In its broad connotation, *regression* refers to the adoption of primitive, infantile, or childish modes of feeling, thought, and behavior, particularly when the individual is faced by difficulties. It represents childish emotional and behavior survivals in older adolescents or adults. Instead of utilizing the method of careful, objective analysis and critical, controlled reasoning, the regressionist reverts to the behavior patterns that brought attention and success in early childhood, such as crying, whining, pouting, displaying

anger or sulkiness, pretending illness, or blaming others for his failures. In psychoanalytic literature, regression is given a special sexual significance. It denotes a retreat of the libido to infantile types of sex satisfaction and to infantile love-objects as a flight from difficulties.

The child may have become a victim of emotional infantilism or arrest of emotional development because of undue parental pampering, fixation, or dependence. The child thus fixated tends to persist in the feelings, thinking, and behavior patterns characteristic of early life. The motive for the regression escape usually operates unconsciously. According to the psychoanalysts, the unconscious motive defends the regressionist against intolerable situations by deluding him into believing that he is not shamming.

Emotional infantilism is a striking characteristic of many neurotics and criminals who employ regression techniques as defense mechanisms against their inadequacies.

The acquisition of regressive trends can be prevented by accustoming the child from early life to a realization that he is living in a real world in which results come as a consequence of effort; by leading him to realize that in the long run no success is genuinely satisfying except self-wrought success; by making each day an adventure in successful living; by avoiding overprotection; and by noticing and commending the child when he is engaging in desirable activities. REGRESSION (READING)—See READING, EYE MOVEMENTS IN.

REGRESSION (STATISTICS). In statistics, regression refers to the fact that as the scores or measurements increase in one variable (usually designated as *X*, the independent variable) there tends to be some corresponding increase in another variable (designated as *Y*, the dependent variable). Any regression at all immediately implies some correlation between *Y* and *X*. The

REJECTED CHILD

trend of the relationship between Y and X is usually continuous and is frequently describable in terms of some mathematical equation.

Linear Regression. The simplest of mathematical relationships or functions is a rectilinear one and the equation which describes it is known as a linear equation. In general terms, the equation of a straight line is $Y = a + bX$, in which a and b are constants for the particular line. The constant b is known as the *regression coefficient*, and it determines the *slope* of the line. If for a certain line $b = 5$, we know that for every unit increase in X the corresponding increase in Y is 5 units. If b were equal to -3 , we would know that for every unit increase in X there is a 3-unit *decrease* in Y . The algebraic sign of b , in other words, indicates whether the line slopes upward (positive correlation) or downward (negative correlation). In fact, b is related to the coefficient of correlation by

the relation $b = r \frac{\sigma_y}{\sigma_x}$, in which σ_x and σ_y

are standard deviations of the X and Y distributions, respectively. The coefficient a in the equation is merely a constant to allow for positions of the two means, M_x and M_y . It is given by the relation $a = M_y - bM_x$. When the correlation between X and Y is imperfect, as is usually the case, there is a second regression equation for the relation of X to Y . In order to avoid confusion, let this equation read $X = c + dY$. Now X is the dependent variable; we are interested in predicting the most probable X from any chosen value of Y , while in the other equation we were interested in predicting Y from

any chosen X . The coefficient $d = r \frac{\sigma_x}{\sigma_y}$,

and $c = M_x - dM_y$. The two regression equations when plotted on coordinates, will be found to describe two different *regression lines*, unless $r = +1.00$ or -1.00 . In this special case the two lines coincide.

Multiple Regression. Similar regression equations can be determined in the case of a multiple-correlation problem. The equation, for a four-variable problem, would read: $X_1 = a + b_2X_2 + b_3X_3 + b_4X_4$. X_1 stands for a score in the dependent variable, and X_2 , X_3 , and X_4 are scores in the

independent variables. The three b coefficients represent the weights to assign to the three scores in combining them. Knowing an individual's three scores in the independent-variable tests, by multiplying them into the corresponding regression weights and summing with a , the most probable score X_1 is estimated. The b coefficients are derived from the intercorrelations of the four variables and the standard deviations of those variables. (See CORRELATION.) J.P.G.

REJECTED CHILD. A rejected child is one who is unwanted by its father, mother, or both. Although most parents are irritated by their children at times, there are some mothers and fathers who are hostile toward their offspring and refuse to take care of or be responsible for them. This rejection may occur at birth (especially if the child is illegitimate); and is illustrated by the refusal of mothers to nurse their infants, name them, or even see them. The father may reject the child if the mother dies at its birth, or if he has reason to doubt its paternity. Moreover, in some cases the child may be unwanted because of economic conditions, marital maladjustment, or because its care may interfere with a mother's social activities or career. The rejection of older children, also, may occur if either parent remarries and feels that the child is in the way.

Rejection is sometimes neither a deliberate nor a conscious process. The motives underlying the rejection may be rooted in the parent's own emotional life and may not be recognized or understood by the parent. Indeed, the parent may not realize that he is rejecting the youngster. Thus, the parent whose third child is a third girl may hesitate to admit the depth of his disappointment even to himself. Another parent, feeling emotionally insecure, may resent the adolescent whose intellectual development is so rapid as to emphasize the parent's mediocrity. On the other hand, a child may feel and react

RELATED INFORMATION — RELIABILITY

like a rejected child when there is no realistic basis for his attitude.

The effect of rejection upon the child's personality and behavior may be serious, as shown by juvenile court and clinical records. Rejection may be the cause of aggressive and rebellious behavior, stealing, lying, truancy, and running away. These delinquencies represent the child's attempt to get attention as a substitute for the affection which is denied him.

Attitude therapy with parents is sometimes helpful, although changing the rejective attitude of parents and re-educating their children are often difficult. About all that can be done for rejected children is to give them responsibilities of which they are capable, together with a reasonable amount of attention, encouragement, and praise. In serious cases, foster parents may be the only solution.

RELATED INFORMATION. In vocational education at the secondary school level, curriculums may have three aspects: (1) shop, laboratory, or field work; (2) related instruction; and (3) non-vocational, general, or cultural instruction. In all-day industrial schools operating under the Smith-Hughes Act, the time devoted to each of the three may, for example, be in the following ratio: shopwork fifty per cent, related instruction thirty to thirty-five per cent, and nonvocational instruction fifteen to twenty per cent.

Each area of vocational education, namely, agricultural, homemaking, trade and industrial, and distributive education, has its special kinds of related knowledge. In trade and industrial education, *related mathematics*, *related science*, *related drawing*, and *related trade theory*, including *safety* and *accident prevention*, are the chief related subjects. These subjects are vocational if they are truly related to the particular vocation. To illustrate, algebra and geometry of the conven-

tional sort are not "related mathematics," whereas the latter may contain arithmetic, algebra, and other forms of mathematics that are selected on the basis of their direct applicability to the "practical" work of the vocation.

Teachers of vocational related subjects must have vocational certification. Their professional training helps to qualify them to select and organize "related instruction" or "related subjects" that function effectively in actual vocational experience.

RELEASED TIME—See RELIGION AND PUBLIC EDUCATION.

RELIABILITY. For every sample of persons used for purposes of generalization in educational research there is a larger "population" of which the sample constitutes only a part. For every "obtained" statistical measure there is a corresponding, theoretical "true" measure. For every educational test there is a body of content from which the much smaller body of test content is drawn. For every "obtained" score on a test there is a corresponding, theoretical "true" score. The sample *represents* the population from which it is drawn, the test content *represents* the larger body of content from which it is drawn, and the "obtained" measure or score *represents* the corresponding "true" measure or score. Reliability is concerned with the degree of conformance or divergence which exists between the "obtained" and the "true" results. The applications of the concept of reliability are numerous and varied. Among those of greatest significance are the reliability of a sample statistic, (mean, standard deviation, etc.), the reliability of a test, the reliability of a score, and the reliability of differences between measures.

RELIABILITY

Methods of determining the reliability of a sample statistic cannot be represented adequately here. The concept involved in each case is concerned with the amount by which the "true" measure may vary from the "obtained" measure and the likelihood that a variation is the result of chance factors.

Reliability of statistical measures. Let us assume that a group of pupils have been tested and the mean of their I.Q.'s determined. Let us assume, also, that the same test (or equivalent tests) is repeated with the same pupils (or with similar samples of pupils) one hundred times, thus yielding 100 means. The reliability of the mean measure for such a group is determined by the extent to which these means vary among themselves. The more reliable the mean, the less will be the variability. Complete or perfect reliability would mean that the arithmetic mean was always the same—never varied. The standard deviation and quartile deviation of such (presumed) distributions of means (or other statistical measures) are called *standard errors* and *probable errors*—the variation being regarded as a measure of lack of reliability or error.

It is important to distinguish between the standard deviation of a set of scores and the standard deviation of derived statistical measures (measures of central tendency, variability, correlation, and the like)—the former are usually called *standard deviations*, the latter *standard errors*. Since means (or other statistical measures) would be expected to vary only slightly, standard errors are generally much smaller than standard deviations. Formulas for standard errors of various statistical measures can be obtained in any standard text on statistics.

The standard error is in effect a standard deviation of a hypothetical distribution. Its interpretation is therefore the same as that for a standard deviation. For example, suppose the "true" mean for a set of measures is 80 units and the standard error of the mean is found, from the formula for the standard error of the mean, to be 1 unit. The interpretation of this fact is that if similar sets of data were obtained for say 100 similar groups, one would expect that 68 per cent of the means of the groups would be between 79 and 81, and virtually none of the means would be below 77 or above 83. Such a theo-

retical distribution of means is presumed to be normal. Another interpretation is that the chances that the true mean differs from the obtained mean by more than one point are 32 in 100. It should be noted that the actual characteristics of such a theoretical distribution of means (the true mean and the exact standard error) cannot, by the very nature of the case, be known. Therefore the known data are employed not to give the actual "true" value of the measure in question, but the probable or expected value in terms of the data available.

The probable error, the quartile deviation of the theoretical distribution of means (or other measures), is often used in place of the standard error as a measure of reliability. It is generally the practice to use standard errors for such measures as means and standard deviations, and probable errors for such measures as medians and quartile deviations. The reliability of a correlation coefficient has been almost universally given in terms of its probable error. Thus, a correlation coefficient which is given as $.91 \pm .02$, is interpreted as meaning that the chances are 50 in 100 that the true correlation is between .93 and .89 (.91 plus .02 and .91 minus .02). This interpretation assumes, however, a normal distribution of r 's and should be used only in the case of large samples.

The concept of reliability is particularly important in educational research since educational measurements are patently subject to the possibility of large error of sampling. Therefore, the interpretations of data must be in terms of a knowledge of the reliability of the data. The degree of reliability determines both the interpretation and the weight to be attached to them. When the mean of a distribution is determined, its standard error (especially when expressed in such meaningful units as months of age) indicates whether it is likely to differ by an amount that makes any use of it questionable.

When data are obtained for a group, it is often important to know how accurately the group represents the population from which it is drawn. The reliability of the sample is therefore of special significance. A particularly important use of reliability refers to the difference between groups. Many research studies compare two groups, for example, in determining the relative effectiveness of two

methods of teaching. The reliability of such a difference is called its *statistical significance* (See SIGNIFICANT DIFFERENCE.)

Reliability of tests. Applied to tests, reliability refers to the consistency of measurement, or the degree to which the test measures whatever it does measure. As these statements imply, reliability is concerned with the self-relationship or internal consistency of the measuring instrument. Reliability is essential to, but not a guarantee of, validity in a test, for a valid test must be reliable, but a reliable test is not necessarily valid; i.e., a test cannot measure what it purports to measure unless it measures what it does measure, but a test can measure what it does measure without measuring what its user intends it to measure. (See VALIDITY.)

The *reliability coefficient*, which is merely a special application of the coefficient of correlation, is commonly used to estimate test reliability when the conditions necessary to its computation prevail. The coefficient of reliability is the correlation coefficient between the scores made by the same group of persons on two equivalent forms of the test successively and comparably administered. It is important that the equivalent forms of the test consist of items similarly chosen from the body of content and that score distributions for the two forms have closely similar measures of central tendency and variability. (See SELF-CORRELATION and SPEARMAN-BROWN PROPHECY FORMULA.)

The reliability coefficient is more useful in identifying poor tests than in selecting good tests, for a test of low reliability cannot possess satisfactory validity but a highly reliable test can, if improperly used, lack validity (*q.v.*) of adequate degree. A reliable and valid test of silent reading ability may be a reliable, but not valid, test of native intelligence. If this test is misused as an intelligence test, the children who get high scores on the test will continue to get high scores when equivalent forms of the test are used, but these scores may not represent the degree of native intelligence.

There are no definite quantitative criteria that can be applied to reliability coefficients to determine when they are adequately high, as test results have many and varied uses which demand varying minimum reliability

coefficients for the tests. For example, a test the results of which are used in individual evaluation should possess much greater reliability than a test the results of which are used for a survey of group achievement. Furthermore, since reliability coefficients depend upon the range of talent, it is impossible to say correctly that a test has a certain reliability coefficient. Rather the reliability of a test should be evaluated for a particular age group, grade group, or a group otherwise selected to represent a range of talent normal for the group to be tested.

Reliability of a score. Increasingly coming into use as a means of evaluating test reliability is a measure of reliability of a single score on a test. The standard error of measurement is obtained by use of the formula:

$$S.D.m = S.D. \sqrt{1 - r_{12}}$$

where S.D. is the standard deviation of the distribution of scores, r_{12} represents the reliability coefficient of the test, and S.D.m is the standard error of a single score. If this standard error is multiplied by three and the product is both added to and subtracted from a single score, the two results are, for practical purposes, the higher and lower limits of probability for the "true" score which the "obtained" score represents. The probable error of measurement, which is .6745 times the standard error of measurement, can be used for the same purpose with minor differences in the method of application. Although these two errors of measurement concepts are presumably not dependent upon the range of talent, their statement of results in terms of the unique scale unit used in the particular test somewhat reduces their ease of interpretation.

RELIEF TEACHER. Relief teachers are employed by the school without being

RELIGION AND PUBLIC EDUCATION

assigned to a class of their own, so that they may be free to serve in the absence of regular teachers. Relief teachers usually serve at reduced pay. When not teaching, they often help regular teachers with individual pupils who need additional attention, visit and observe other teachers, and assist with clerical work. It is generally believed that the number of relief teachers should be approximately ten per cent of the total number of teachers. Some school systems do not employ relief teachers but rely on the use of *substitute teachers* who are engaged, often on a per diem basis, to take the classes of teachers who are absent. D.H.C. and A.R.A.

RELIGION AND PUBLIC EDUCATION. Legal Status. The first amendment to the Constitution of the United States stipulates that "Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof." This prohibition applies to the federal government, not to the states; the constitution contains no provision for protecting the citizens of the respective states in their religious liberties. As Justice Story wrote a century ago, "... the whole power over the subject of religion is left exclusively to the State governments, to be acted upon according to their own sense of justice and the State constitutions." (*Commentaries on the Constitution*, 5th ed., Section 1879.) The Supreme Court has upheld this policy, consistently refusing, for example, to render decisions on such problems as Bible reading in the public schools; it has maintained that such decisions, in the words of the Tenth Amendment, are "reserved to the States respectively or to the people." Practically every state, however, has established constitutional or statutory provisions which expressly prohibit sectarian instruction in the public schools, and in all states such prohibitions are either expressed or implied.

Arguments Against Religious Instruction in the Public Schools. Those who defend the secularization of our public school system point to history for the vindication of their viewpoint. Before the Revolutionary War ten of the British colonies had adopted state religions—seven the Anglican faith, three the Congregational faith. During and following the Revolution, however, state religions, religious tests, and public taxation for religious purposes were gradually abandoned;

by 1833 every state had adopted the principle of the separation of church and state. Upon this foundation was built a system of free, public, tax-supported, nonsectarian schools. Had another policy been followed, the argument runs, there would have been not one public school system in each state, but a number of denominational systems, each teaching its own doctrines and each competing with the others for a share of the public funds. The democratic school system based upon the principle of equal educational opportunity for all has been made possible in part by the secularization of the public educational institutions. The advocates of a secularized public school system deny that religion can be taught without a creedal emphasis. The many varying interpretations make it difficult to reduce them to the dimensions of the classroom. There is the Catholic and the Protestant, the Christian and the Jew, the orthodox and the unorthodox, the fundamentalist and the liberal, the sacramentarian and the evangelistic, the believer in God and the atheist. In view of this situation the teaching of religion in the public schools would engender bitter controversy. Moreover, to compel a pupil to listen to an interpretation contrary to his own religious beliefs would deprive him of his traditional right to religious freedom. Instruction in religion, this group insists, properly belongs not to the public educational institutions but to the home and the church.

Arguments For Religious Instruction in the Public Schools. Those who wish to see the public schools assume an active part in the religious instruction of children and youth contend, in the first place, that the development of virtue and the realization of a complete life, which is a life in God, are possibly only through religious education, and that the state should do everything within its power to facilitate such instruction. To remain aloof is to follow a philosophy of paganism. In the second place, they argue, the nation which secularizes its public schools is actually aiding the forces of irreligion. When a state refuses to use its schools to develop religious virtues, as Bishop John Lancaster Spalding, the Catholic educator, once wrote, "it fatally, though possibly unconsciously and negatively, commits itself to an irreligious and infidel propaganda; since to ignore reli-

RELIGION AND PUBLIC EDUCATION

gious doctrines, while striving to develop the intellectual and moral faculties must result in gradual extinction of faith." (Merle Curti, *The Social Ideas of American Educators*, p. 358.)

Those who advocate religious education in the public schools point out, in the third place, that the Hebrew-Christian tradition has been basic in the formation of Western culture. No one who neglects the religious aspects, they argue, can hope to understand the history of Western civilization. Nor can it be ignored that the church is a vital institution in our society and, in this sense alone, is as worthy of study as the home, the school, the government, and the economic system. Finally, religious education is defended as a method of developing social consciousness. Through religion, individualism can be controlled and the brotherhood of man established.

Current Practices. In actual practice several expedients have been adopted in an effort to make school children more conscious of the importance of religion in their daily lives. The public schools, unable to conduct religious activities of a sectarian or doctrinal nature, have been limited (1) to elective courses in religious subjects, principally in Biblical literature, and (2) to Bible reading and devotional exercises at the opening of each school day. Many individuals have felt that these activities were hopelessly inadequate, and an increasing number of schools have followed the practice of (3) releasing pupils for a certain number of hours each week in order that they might receive religious instruction from the church of their own choice. Those who believe that religious education should be an integral part of all instruction have been dissatisfied with the "released-time" device; it is they who have been responsible for the establishment of full-time denominational schools.

(1) *Elective courses in Biblical literature.* Elective courses in Biblical literature are found in only a negligible number of the public schools. According to a study made by the United States Office of Education in 1938 such courses were limited in 1933-34 to 119 public schools located in seventeen states. There were 4,460 pupils enrolled in these courses. Only 539 of the boys and girls were in grades seven and eight; the remainder

were in high school. Approximately 70 per cent of the students were enrolled in full-year courses; the rest, including all of those electing the work in the seventh and eighth grades, were registered in half-year courses. Two-thirds of the public schools offering the elective courses were located in three states—Indiana, Iowa, and North Dakota; practically all of the other Bible courses were to be found in the schools of the southern states. It is obvious that the practice has not been popular. Those who wish to keep the public schools completely secular are not interested in Bible courses, while those who are eager to have the public schools take an active part in religious education do not believe that a study of the Bible merely as a literary record has much value.

(2) *Bible reading and devotional exercises.* Bible reading and devotional exercises at the opening of the school day must remain, like courses in Biblical literature, nonsectarian and nondoctrinal. But since the determination of what constitutes sectarian instruction is a problem which each state must decide for itself, this formula is difficult to apply. As a result the legal status of Bible reading varies widely among the forty-eight states. Figures released by the Office of Education in 1930 indicated that in twelve states, by court decisions, by opinions of attorneys general, by rulings of state superintendents of education, or by general consent, the reading of the Bible in public schools has been held to be unlawful. In eleven states and the District of Columbia Bible reading is required, in six it is specifically permitted, and in the remainder it is generally construed as permissible.

The provisions of the laws making Bible reading mandatory differ from state to state. In some cases the law stipulates the minimum number of verses that must be read—Delaware and New Jersey require five, Pennsylvania and Tennessee ten, Idaho from twelve to twenty, and Georgia at least one chapter. The Lord's Prayer must be repeated each day in the public schools of the District of Columbia and New Jersey. The Maine statute suggests that special emphasis be placed upon "the Ten Commandments, the Psalms of David, the Proverbs of Solomon, the Sermon on the Mount, and the Lord's Prayer." In Idaho the "standard American version of the Bible" must be used. New Jersey requires

RELIGION AND PUBLIC EDUCATION

that all readings be taken from the Old Testament. In Tennessee, teachers are not permitted to read the same chapter more than twice in any school session.

Several states provide penalties for failure to perform this duty. The first offense in Delaware is punishable by a fine of \$25, the second by a revocation of the teaching license. Kentucky also provides for the revocation of licenses, while the laws of Pennsylvania and Tennessee state that a teacher may be discharged for neglecting the devotional exercises.

Four laws—those of the District of Columbia, Florida, Idaho, and Maine—state that there shall be no sectarian or denominational comment by the teacher. The law of Idaho expressly states that when a pupil raises a question about any portion of the Bible reading the teacher must, without any comment, refer the child to his parents or guardian for the answer.

These are the legal provisions of only eleven states and the District of Columbia. It is difficult to say just how these regulations are observed in the classrooms of the states requiring or permitting Bible reading or devotional exercises. It is clear, however, that the practice of holding devotional exercises, where it exists at all, varies greatly from state to state. The advocates of religious education in the public schools find little over which to become enthusiastic in laws which permit merely the daily repeating of the Lord's Prayer and the reading of a few verses from the Bible. All too frequently such devotional exercises become mechanical and meaningless.

(3) *"Released-time" programs of religious education.* This situation has led to the "released-time" programs of religious instruction. The purpose of these programs is to supplement the secular work of the public schools, "to round out," as the Vermont Council of Churches expressed it, "a more satisfactory educational experience of the pupil by guiding him in a discovery and experience of the spiritual and Christian elements of life." Although there is considerable variation, the tendency is for the religious classes to meet one day each week during the school term for a period of approximately sixty minutes, usually the last hour of the school day. Pupils excused in most cases are

released from school usually only upon the written request of their parents to attend the religious class of their own choice. About 57 per cent of the classes are held in church or other buildings off the school grounds, 41 per cent are held in the school buildings, and the remainder divide their locations among the school buildings and other centers. Major emphasis in the curricula is upon Bible study, although character education, good citizenship, and church doctrine also receive a large amount of attention. According to a study published in 1941 by the United States Office of Education (from which these and the following data are taken) credit toward graduation was granted by 96 schools, while 140 institutions did not grant credit for the released-time work. There seems to be no fixed policy for dealing with those pupils who do not elect to take the courses in religion. Some continue their regular classes, others have study periods, engage in remedial work, make up back assignments, review previous lessons, do recreational reading, or receive instruction in morals, manners, ethics, and citizenship.

The released-time schools are organized and administered along three general lines. In most cases the individual churches of the community accept the responsibility for their own schools. A few of the released-time schools are run along cooperative lines, with an advisory council of all churches, but with each denomination providing its own curriculum and instructors. Many of the schools are run by an interdenominational council, which provides buildings, curriculum, and instructors for the pupils of all denominations. There are, of course, variations of all these administrative arrangements.

Teachers are secured in a number of different ways. The religious organizations appointed 59 per cent of those reported in the study made by the Office of Education; 37 per cent were appointed by religious organizations and approved by the local boards of education; and 4 per cent were appointed by public school officials. About 35 per cent of the teachers were paid; about 40 per cent were volunteers; and ministers and priests constituted the remainder.

The first released-time program appears to have been started in Gary, Indiana, in 1913. Since then this type of activity has become

RELIGION AND PUBLIC EDUCATION

increasingly popular. In 1940 there were more than 455 of these schools in all parts of the country. Returns from 357 of the schools showed an average attendance of 164,013 pupils, of whom four-fifths were from the elementary schools, one-fifth from the high schools. It is estimated that released-time programs are available for children in one of every eight towns or cities, with populations of 2,500 or more; in the smaller towns and rural areas this type of educational program is much less frequently encountered.

The released-time activities raise a number of perplexing legal questions which, in many states, remain partially or wholly unanswered. Do the laws prohibiting the use of school buildings and funds for sectarian instruction also prohibit the use of public school time? Does the practice violate the compulsory attendance laws which require attendance for the "full" or "entire" school day? May attendance upon religious instruction be coerced, directed, or supervised by public authorities? Can credit be given by the public schools for religious work done outside the school but on school time? Is it religious discrimination to release some pupils for religious instruction while others are retained for the remainder of the school day? In an effort to deal with this type of problem eight states have provided legislative authorization for the release of pupils during school hours. The released-time programs have been authorized in fifteen other states by rulings of the state attorneys general, by court decisions, or by opinions of the state boards of education or the chief school officials. In three states—California, Oregon, and Washington—the attorneys general have ruled against releasing pupils from regular school time. The laws of the remaining states are silent upon the subject.

There are many who believe that the released-time programs will put religion back into public education, making it a vital part of the child's daily experience. Once this is done, both the church and the public school will become more meaningful. These persons contend that this type of religious activity will help to improve all religious education because it will force greater attention upon curriculum, equipment, and teachers. They maintain also that through released-time activities the unchurched may be reached. (At present more than one-half of all the boys and girls

in the United States receive no religious instruction outside the home.)

Others do not accept these optimistic beliefs. They argue that released-time programs do not actually solve the problem, for religion is still not treated as an integral part of our culture. Nor can religious attitudes be developed in an educational program that operates for only an hour or so each week. Indeed, they insist that released-time activities are harmful. By focusing attention upon issues which divide men rather than on principles of conduct upon which there is general agreement, such activities accentuate differences, divide families in which religious differences exist, create dissent among children, and tend to arouse hatred and intolerance. For this reason, they contend, released-time programs of religious education are undemocratic. This group also rejects the idea that there should be an intimate relationship between the public schools and any kind of religion. The best solution to the problem of religious education, it is argued, is to reduce the length of the school day and dismiss all pupils, letting them decide what to do with this free time. Finally, the opponents of the released-time activities point out that the Supreme Court of the United States has maintained that there can be no determination of what is and what is not religious. As a consequence, where released-time programs are in effect, a pupil would have to be released from public school even if he chose to attend classes run by sects or organizations which were not accepted by the majority in the community.

(4) *Parochial schools.* Many believe that none of these solutions—elective courses in Biblical literature, devotional exercises and Bible reading, or released-time activities—is really adequate, but that religious instruction must be an integral part of all education. Moreover, each denomination tends to the belief that its interpretation of the Bible is the correct interpretation. As a result, those denominations which have been able to afford it have established their own systems of parochial schools. Nearly ten per cent of America's children and youth are today receiving their education in denominational schools. Although the vast majority of these boys and girls are Catholics, over a score of other religious denominations are conducting their own educational programs. There are some who object to the parochial school program

on the grounds (1) that it serves to emphasize the divisions in society and is, therefore, undemocratic, and (2) that a dual system of schools is both expensive and inefficient.

REMEDIAL INSTRUCTION. Teaching in such a way as to remove persistent difficulties in learning is known as *remedial instruction*. After the diagnostic steps have revealed the shortcomings and their causes, procedures are planned to correct the weaknesses with appropriate learning exercises. The nature of the difficulty must be understood, otherwise the remedial teaching may be merely a continuance of the original teaching and thus be ineffective. If the errors in learning result from failure to make certain associations habitual, drill may suffice to overcome them, but drill as the only remedial procedure generally proves unsuccessful because it usually does not modify causative factors. The learner as well as the teacher should know why the mistakes occur and how the remedial work will help to correct them.

Knowledge of the psychology of the learning process is essential for the teacher to plan effective remedial instruction. It has been shown, for example, that pupils make errors in an algebraic process, not because of lack of drill but because of lack of understanding or sense of mathematical operations. If the length of a rectangular field is given as x

yards and its width y yards, and the answer derived is $x+y$ yards for the area, the remedy is not more drill but the attempt to create an understanding of how areas are found and the formulation of the proper algebraic equation. Remedial teaching frequently requires building an experiential background so that learning by words or textbooks has meaning in the lives of young people. This concept of remedial teaching applies particularly to subjects based upon the objective world and its forces, such as physics, the social studies, botany, biology, nature study, mathematics, and symbolic representation in literature. Vocabulary building, right processes in reading, greater speed and accuracy in mathematical manipulation, correct use of grammar, better spelling, and facility in oral expression are common objectives of remedial teaching, but these objectives have basic psychological foundations which must be understood by the person giving the remedial instruction.

The common practice is for the regular classroom teacher to attempt to remedy the deficiencies displayed by her pupils. In some cases, special classes, such as classes in remedial reading (*q.v.*), are provided for deficient pupils and are taught by especially qualified teachers. Since diagnostic testing and remedial instruction are considered feasible in classroom teaching, there is a strong tendency to hold all teachers wholly or partly responsible for the correction of difficulties in learning.

Procedures for remedial work in the tool subjects have been developed, such as individual work books with self-corrected practice tests that are used in arithmetic and grammar, and flash cards that are employed for word recognition and reading span. These and similar devices can be worked out for the drill or near drill phases of subjects. In more complicated areas of learning, the teacher must reteach—on an individual or group basis—after a careful diagnosis of the intellectual, physical, emotional, and volitional causes of difficulties. In the final analysis, remedial teaching is differentiated and intensified instruction, with specific and well-defined objectives. (See DIAGNOSIS, EDUCATIONAL; READING DISABILITY.) F.A.B.

REPRESSION. The psychoanalysts attach considerable importance to repression, which they look upon as the mechanism of psychological adjustment through which libidinal wishes, the urges to love and to aggressiveness, are forced into the unconscious mind when they are unacceptable to the ego and the super-ego. This resolves the conflict which may occur in a situation where intense fear develops with regard to the consequence of carrying out some wish. Repression is frequent in childhood where the weak ego of the child is unable to cope with the real or imagined consequences of some of his loves, hates, and aggressive wishes. Thus, at different stages of his development the child finds his love impulses restrained and frustrated. His love of his mother is frustrated by the attention the mother must of necessity give the father. This develops jealousy of the father but also fear of the consequences of this hostility. It is this hostility and fear of the consequences which leads to childhood repression. Some repressions are successful in that the repressions remain fairly dormant in the unconscious. In many cases, however, the conflict and the repressed energy are converted into psychic or organic disorders.

J.F.B.-2

RESEARCH, EDUCATIONAL. Efforts to define educational research are beset with difficulties. On the one hand, there is still considerable dissension as to whether education should be viewed as a science, a technology, or an art. On the other hand, there is the question of whether all careful study of a subject should be viewed as research, or whether to be known as research an investigation must conform to traditional canons of scientific procedure. When one views the several issues affecting definition, one is tempted to paraphrase the psychologist who remarked that psychology is that which psychologists choose to study, and to say that

educational research is that which educational researchers do. There is much merit in this apparently illogical approach, for educational research is not simply an abstract concept; it is a dynamic movement in contemporary education. The institution is the practical reality. It can best be described in terms of the interests, ideas, and behavior of its participants.

The ways in which educational and related cultural trends have developed since 1890 have had a marked influence on the research movement. The swift expansion of the whole enterprise of public education, with its involvement of more pupils, more teachers, more schools, more courses, more regulations, and more expenditures, was bound to awaken interest in a host of new problems. Industrial expansion, a broader national outlook, and changing philosophical and psychological theories resulted in strong pressures for a re-examination of educational theory and practice. The dominant note in the intellectual upheaval which marked the early years of the educational research movement was utilitarian and pragmatic in character. While in the 1880's there had been growing interest under G. Stanley Hall in child study and in biometrics as an essentially pure scientific field, the first sharply delineated trend in educational research stressed the determination of school efficiency by means of empirical surveys. The development of objective measures of school attainment and of learning capacity went hand in hand with the expansion of the survey movement. Laboratory and then school experimentation were used as instruments for increasing learning and teaching efficiency. Statistical methods were necessary adjuncts to surveys and experimental studies; the development of educational statistics further stimulated these investigations as did the numerous advances in techniques for devising measuring instruments. The acceptance of specifically utilitarian and supposedly objective and functional bases for evaluating and constructing curricula encouraged a multitude of curricular investigations, many of them utilizing counting devices of one sort or another. By 1925 the "objective, quantitative school" seemed to have conquered the field. Thousands of piecemeal, quantitative reports occupied the great majority of the pages of education publications.

The educational philosophers, however, never fully accepted the implications of the narrow quantitative-efficiency trend of thought. True, there were the die-hards of the pre-research school. But there were also the adherents of progressive education who saw in the cut-up approach to educational means and outcomes a violation of the principle of education as organic growth. They objected to the emphasis on measurable outcomes, holding that changes in the integration of the child's personality and in his capability for adaptation to new situations—both intangible—are more significant than specific modifications in skill and knowledge which are readily measured. The effect of the broader, dynamic influence is apparent in numerous evidences of a breaking down of the early attempt to ape the physical scientist in the application of research techniques. There is today greater recognition of the rôle of evaluative and synthetic thinking in educational research and fuller acceptance of the view that research method is not an iron-bound procedure but rather the refinement of the process of problem-solving. Consequently the methodology of research follows the nature and needs of the problem situation. Such a view welcomes the utilization of all techniques that are appropriately applied. It is only when one senses the many-sidedness of the problem of educational ends and means and seeks to integrate the diversified efforts of educational researchers that one can detect threads of orderliness in the apparent chaos of research endeavor.

Several additional features of the research movement in education merit mention. Research in education has been a relatively popular movement. Most of its contributors are not professional researchers. Only a small proportion of those who conduct studies ever carry on more than one or two investigations. Many research projects are conducted incidentally along with graduate professional study or regular teaching or administrative assignments. In fact, the research function is often found to be interwoven with such other functions as supervision, administration, and propaganda. The necessity for working with pupils and materials in regular school circumstances naturally tends to restrict freedom of research enterprise. Practical difficulties, limited financial support and personnel, and

the complexity of the really significant educational problems cause many of the studies to fall short of acceptable standards of dependability and usefulness. In spite of relatively wide participation by educational practitioners, there is a marked lag between research results and their application to practice. However the contemporary picture is noticeably brightened when one observes the marks of progress made since the inception of the research movement.

Especially encouraging has been the institution of cooperative research agencies and enterprises. Even where research continues to be done on an individual basis, cooperative efforts in the form of bibliographic aids and coordinated publications serve to improve the quality and enhance the utility of research studies. Notable instances of such sources are the *Review of Educational Research* and the *Encyclopedia of Educational Research*, both published under the auspices of the American Educational Research Association. These summarizing treatises help consolidate research advances, outline needed investigation, and prevent wasteful duplication of effort. The Yearbooks of the National Society for the Study of Education demonstrate how the work of leading educators can be coordinated in the study of the subjects selected for treatment in the annual volumes.

In recognition of the need for permanent organization and concerted effort, research bureaus have been established. A bureau of educational research has been defined as "a special corporation or definitely created subdivision of a school system, teacher-training institution, university, or state education department, organized for the purpose, first, of exercising functions of reference or investigation, second, of organizing and directing the investigational activities of others, or third, of serving both these purposes." In spite of their diversification, research bureaus have helped to bring a modicum of continuity and cumulative progress to the research movement, which had been generally marked, at first, by a lack of systematic planning and control. While on the one hand the bureaus represent a reaction against the inefficiency and futility of uncoordinated individual research effort, they have on the other hand fallen in line with the American conception of educational research as a popular movement among school personnel and have done

RESEARCH, EXPERIMENTAL

much to stimulate and direct individual initiative in research enterprises. (See RESEARCH, EXPERIMENTAL; SCIENTIFIC METHOD IN EDUCATION.) H.H.A.

RESEARCH, EXPERIMENTAL. Reduced to its elements of methodology, experimental research refers to a procedure whereby the effects of specified factors are ascertained through control and measurement. In practice, the forms of experimentation have been diverse. Two major classes of experimental investigation are commonly referred to: laboratory studies and classroom or school experiments. The former, as contrasted with the latter, have had a somewhat longer history; tend to utilize fewer subjects, who frequently are adults; and entail stricter control and measurement, often utilizing especially designed apparatus. Outstanding groups of laboratory experiments have been made in the analysis of eye movements in reading, in the determination of the course and economy of learning, and in the description of animal drives and behavior. Ingenious investigators have more recently carried laboratory techniques into the realm of social behavior and personality.

The demand by practical educators that methods and principles be tested under normal working conditions precipitated a swing toward school experimentation in which experimental conditions, materials, and personnel were more representative of applicational situations. School experiments have ranged from minor variations in the presentation of a single lesson with a single class to fundamental methodological and curricular distinctions as applied over a period of years to entire schools or groups of schools.

The value of experimental research in education has been made the subject of interest-

ing speculation, as have the relative merits of laboratory versus classroom experimentation. There is wide agreement, however, that the application of experimental techniques by educators has been far from perfect but that a steady maturation process is apparent. At worst, the experimental movement in education has been a stimulating challenge; at best, it may become, as its early adherents hopefully claimed, the spearhead of the drive to achieve for education the dependability of thought.

Experimental Method. Experimental method involves an attempt to control all essential factors save certain variables which are manipulated with a view to determining and measuring the effect of their operation. The essence of experimentation lies in this actual manipulation of conditions and observation of consequent effects. It is probably the most powerful weapon of scientific method, its findings being subject to universal confirmation at will.

There are two general types of experimentation: one type stresses the importance of varying the essential conditions only one at a time ("law of the single variable"); the other emphasizes simultaneous variation of several factors ("factorial design"). The latter approach, introduced recently by R. A. Fisher, is presumed to yield increased efficiency and information and is beginning to attract considerable attention. The former approach is exemplified by the three patterns of experimentation introduced and popularized by W. A. McCall: the single-group, equivalent-groups, and rotation patterns. The publication of McCall's *How to Experiment in Education* opened the field for scientific experimentation in education.

The most feasible but usually the least valid plan of experimentation is the single-group pattern, which does not conform strictly to the definition of controlled experimentation. Essentially, it involves the administration of two or more experimental factors to the same group, each factor being preceded and followed by a test. The relative effectiveness of the experimental factors is judged by the size of the difference between the result of the test administered at the beginning of the experiment and the result of a comparable test administered at the end of the experiment. The major limitation of the single-group method is that it is frequently almost impos-

sible to disentangle the effect of the experimental factor from the effects of other concurrent factors. This limitation is obviated by the equivalent-groups pattern, which provides for experimental and control groups, thereby offering a basis for discounting the effects of factors other than the experimental factor. The control group is selected so as to be equivalent to the experimental group with respect to those traits that may influence the operation of the experimental factor. However, the danger involved in the equivalent-groups pattern is that the groups may not be equivalent, even with respect to the traits that are involved in the experiment. The rotation pattern surmounts the limitation of unequal groups by having two experimental groups and by applying each factor to each group in alternate order.

Factor design involves a complex, unsystematized rotation pattern. It breaks the experimental group into as many sub-groups as there are experimental factors, each group receiving each experimental factor in a purely randomized order, subject to certain minor restrictions. This design is specially adapted to the statistical treatment termed "analysis of variance". (See EQUATING GROUPS.)

RESEARCH METHODS IN EDUCATION. Research methodology in education refers to the application and adaptation of the principles and procedures of scientific inquiry to problems of education. Certain of the tenets of general scientific method are applicable to education with little or no modification, but many of the concepts and techniques employed in other fields require adjustment to special circumstances when used in the educational area.

Aside from bibliographical reference and the use of such tools of research as statistical

analysis, there are four major types of research method: the descriptive, causal, evaluative, and constructive types.

As its name implies, the descriptive method serves to gather and to arrange data in meaningful contexts without seeking to ascertain cause and effect relationships, without evaluating the conditions revealed (as far as that is possible), and without constructing positive plans or programs. There are two aspects to the method: that of approaching or ascertaining the alleged facts, and that of arranging facts in significant patterns.

Educational data may be approached through five media: direct observation, testing, interviewing (*q.v.*), applying questionnaires (*q.v.*), and referring to written sources. Any or all of these may be employed in a single study. Often one approach is used as a check against another. Much has been written about the necessity for strict objectivity in the approach to data. Many attacks have been leveled against the use of the questionnaire and other approaches which seem to rely in large part upon subjective judgment. Some writers, recognizing the restrictions that would result from the use of objective data alone, have advocated the use of the relatively subjective data where the more objective methods either are not available or would not yield equally fruitful information.

The data gathered through the several fact-finding media may be arranged in any of a large numbers of patterns according to the purpose of the study. Chronological arrangement is, of course, common in historical studies. Comparison of age groups reveals genetic trends. Coordinate plottings of data may serve as the basis for predictive estimates. As long as causal relation, evaluation, or construction is not treated focally, an investigation may be regarded as descriptive regardless of the nature or intricacy of the organization of the data.

The line of demarcation between associative descriptive studies and causal research is very thin, but evident. To demonstrate that the graduates of High School A have been consistently superior in college to the graduates of High School B does not prove the superiority of the curriculum or methods of School A. The elimination of all other potentially influential factors would be required to demonstrate causal relation.

There are two general approaches to the study of causation; the experimental and the non-experimental. The experimental method (*q.v.*) entails the manipulation of conditions and the observation of the resultant effects. The non-experimental approach involves the determination of the degree of association among phenomena, reenforced by speculation concerning their mode and direction of operation. It is sometimes called the inferred causal method. This method attempts to determine the causes of observed effects, working from the effects backward. It is an equivalent groups experiment in reverse. Those factors which differentiate between the two groups are ordinarily studied further as possible causal factors. Where groups are not equivalent, adjustments are attempted in order to duplicate conditions necessary for fair comparisons. At times complex statistical analyses are applied in an effort to isolate causal factors.

It is generally agreed that an experimental comparison of two educational procedures may indicate what are the effects of each of the procedures. But the desirability of the several effects still has to be ascertained before one can determine which of the two means is to be preferred. Some writers have declared that this is a problem for the philosophy of education and not for scientific research. An opposing view holds that research, while utilizing objective, quantitative data as far as possible, cannot avoid the responsibility of applying to all significant problems the most dependable techniques available even though they may not be entirely objective. According to this view, evaluative problems and hence evaluative techniques fall within the province of educational research.

Although the evaluative method is necessarily subjective, in the hands of the careful research worker it exemplifies the controlled utilization of subjective judgment. Factors undergoing evaluation are carefully described, as is the setting or the frame of reference in which they are to operate. Criteria are explicitly stated and their rôle in the total evaluation indicated so that persons operating in terms of other criteria or emphases can readily bring their differences to bear in further study of the problem. Criteria, and the things to be evaluated are functionally analyzed to avoid vagueness and

generality. Specific judgments in the application of criteria are overtly reported. Provision is made for both differentiation and integration in the final judgment of value. (See also EVALUATION.)

As in the case of evaluation, issue has been raised as to whether applicational construction falls within the scope of educational research. The expression "scientific curriculum construction" has been widely used, but the context in which the term usually occurs connotes a descriptive rather than a constructive approach. The desire at one and the same time to remain within the confines of objective description and to make constructive recommendations has led to such incongruities as the attempt to build curricula principally or solely on the basis of frequency counts.

In fact, constructive research entails more than description, although reference to pertinent facts plays a significant role in this as in every type of research. Construction is essentially a cumulative and culminating process in which the findings of descriptive, causal, and evaluative investigation are utilized in building an integrated program. Prominent features of construction are the systematic search for and evaluation of suggested elements, and the synthesis of those elements which are acceptable.

The foregoing account of the basic methods of research would seem to imply that no list of clear-cut, mutually exclusive research procedures is available. That is precisely the case. One method flows into the other; most investigations of major scope entail the use of several methods. What holds the procedures together in any given project is the logic of the solution to the problem at hand. There is no substitute for sound reflective thinking. All that research methods signify is that thinking will be as systematic, unbiased, and factual as circumstances permit. (See RESEARCH, EDUCATIONAL.) H.H.A.

RESERVE OFFICERS TRAINING CORPS—See MILITARY EDUCATION.

RESIDENCE REQUIREMENTS. *Residence requirements* refer to the length of time and the period one must attend a college or university in order to receive a degree from it. The almost universal practice on the part of colleges or universities is to require one year residence as a minimum, usually the last one before receiving the degree. Minimal residence requirements for professional degrees and for the doctorate are frequently more than one year.

Residence requirements limit the amount of nonresidential education that may be offered toward the degree. (Correspondence courses and completely independent study are examples of nonresidential education.) The institution awarding the degree can, and frequently does, test this work; however, although practice varies widely, only a small part of the degree requirements may be met by work done independently of an educational institution. In schools of recognized standing no credit for nonresidential work is given toward the professional degrees or the doctorate.

R.A.K.

E. A. FITZPATRICK, "Residence Requirements for the Doctor's Degree", *Journal of Higher Education*, X: 381-388, October, 1939.

RESOURCE PEOPLE. Resource people is a term used to describe one of many approaches to systematic community study through the schools. The phrase is applied to those lay persons who (a) possess cultural backgrounds, special abilities, particular accomplishments, or other achievements which are of value and interest to school pupils, and who (b) are both willing and able to discuss, demonstrate, display, or otherwise personally present their attainments before a class or school assembly. Resource people are best utilized to provide serious and realistic educational experiences for pupils rather than only to interest or entertain them. The immigrant mother who sings old-world folk songs for the first grade, the fireman who stresses safety for the ten-year-olds, the editor who explains newspaper policies to a high school group, and the banker who discusses inflation before a college class are illustrative instances of resource people well utilized for purposes of significant and vitalized education.

If the resource person is to make his optimum contribution, both the speaker and the class should be prepared for the visit. The

consultant can develop his material more effectively if he knows beforehand the nature of the problem on which the class is at work, the progress the group has made in its study of the topic, and the areas in which help is needed. The students, too, should prepare in advance by summarizing the progress they have made in the solution of the problem and by formulating the kinds of questions on which they hope to secure help from the visitor. Following the interview, the group again should evaluate progress in the light of the contributions made to their study by the resource person consulted. (See COMMUNITY AND SCHOOL.)

E.G.O.

RETAIL SALES EDUCATION — See DISTRIBUTIVE EDUCATION.

RETARDATION—See PROMOTION.

RETESTING. The second administration of a test to a pupil after a lapse of time is referred to as retesting. Retesting is used when one wishes to obtain a measure of pupil improvement or consistency. In order to provide a more satisfactory means of measuring these qualities, two equivalent forms of the same test should be used, thus avoiding repetition of the same test items.

Two or more forms of a test are said to be *equivalent* when they are based upon the same material and contain items which are similar in type. When administered to the same group, the distribution of scores obtained should have equal means and equal variability.

When a second test consisting of exercises similar in type and difficulty is administered within a few days after a pupil has first been tested, the scores on the second test generally will be higher. This increase, which is due in large measure to the pupil's acquaintance with the type of test being used and his familiarity with the general conditions under which the testing takes place, is ordinarily referred to as *practice effect*. The effect of practice, then, is to introduce a constant error in test results. While the increase owing to practice effects varies from test to test, and in some types of tests has been found as high as ten per cent, in most cases previous practice is not likely to cause serious error in the scores obtained if a considerable time elapses between tests, unless there has been a definite attempt to coach the pupils involved.

RETIREMENT, TEACHERS' — REVIEW

The correlation between the results obtained through retesting, using either the same test twice or equivalent forms of a test, may be used as a measure of the reliability of the test. J.J.

RETIREMENT, TEACHERS' — See **TEACHERS' RETIREMENT.**

RETROGRESSION — See **REGRESSION (PSYCHOLOGY).**

REVERSALS. A reversal in reading or writing is an error involving a change from the correct order of symbols, or a confusion of symbols which are similar in shape but different in spatial position. Reversals may involve (1) confusion of single letters such as *p* and *q*, *b* and *d*; (2) partial reversals of words, such as *arm* for *ram*, or *blind* for *blind*; (3) complete reversals of words, such as *on* for *no*, *was* for *saw*; and (4) reversals in the order of words, as "The worm saw a bird" for "The bird saw a worm." Reversals may also be found in reading and writing of numbers. They are found in some but not all cases of reading and spelling disability. (Compare **STREPHOSYMBOLIA.**) A.J.H.

Reference.

A. I. GATES and C. C. BENNETT, *Reversal Tendencies in Reading* (Teachers College, Columbia University, New York, 1933).

REVIEW. Review is a teaching procedure which aims at helping students to get a new view or a richer understanding of relationships that have been studied. The students' initial study of a major topic is often incomplete and lacking in significant respects, and a review serves to round out the picture and emphasize the essential relationships.

Thus a class in economic geography which has been studying the rôle the railroad has played in the development of the United States may gain new insight into the significance of transportation by attempting to predict the effect that the extension of large scale air transport would have on the future importance of such cities as Chicago and New York. Review is not mere repetition or reteaching of the same material in the same manner. Review is reteaching only in the sense that it uses subject matter and skills that are familiar to the student, but it approaches his material from a different point

of view and involves student activities that should be as well motivated and as vital to the student as any in which he has engaged.

Review is a teaching procedure rather than a form of drill or a means of testing. Drill (*q.v.*) aims at improving retention by making certain responses automatic; review improves retention by broadening and clarifying the student's understanding. A mathematics teacher, for example, may drill on locus theorems in geometry by having the student do a number of simple exercises with a fixed time limit; he can review the locus theorems by helping the students to understand other applications of the principles than those which were used when the principles were first taught. In like manner, a review has some of the characteristics of a test. A well-conducted review often reveals mistaken points of view and other misunderstandings, but the primary purpose of the review is teaching, not testing. Reviews should not be confused with cramming, which is much like drill in its attempt to improve retention.

Review serves several important purposes: (1) It provides for a restatement and organization of what has been studied to assure understanding and fix important facts; (2) it provides for the unification of the work by helping pupils to see the larger wholes and relative values; (3) it gives pupils a broader perspective of what is being studied; (4) it provides an occasion for the use of supplementary material to make the work more vital and interesting; (5) it provides a foundation for new work that is to be introduced; (6) it helps the teacher discover weaknesses of pupils and enables him to provide for further teaching or remedial work; (7) it reveals weaknesses in teaching; and (8) it is a good means of giving pupils practice in thinking through problems and organizing the relationships being studied, as well as testing their ability to do this.

In planning reviews several factors should be considered—the frequency, the length of the review period, the selection of material to be reviewed, and the procedures to be used—factors that necessarily vary with the class and the subject. Many teachers use a brief "daily review." Although this short, frequent review may be used to advantage, it is apt to degenerate into simply a testing or a drill period. In practice, reviews are conducted

most frequently after the class has almost completed its study of a significant area of subject matter. Reviews vary in length from review questions that require only a part of a single classroom period for discussion and solution to projects that may take a week or more. Pupil participation is as important in reviews as it is in all other teaching procedures. Thus a cooperative review in which pupils and teacher work together to prepare an outline or a chart showing the important relationships that have been studied is better than the teacher-made outline which students are so often asked to copy. What distinguishes the review from other types of teaching procedures is its purpose rather than its form. Reviews may be conducted, therefore, by using such different procedures as pupil reports, discussion of new problems, lecture-demonstrations, panel discussions, projects, etc. When reviews are carefully planned they are an integral part of the term's work rather than separate appendages. Thus, having the students make practical applications of a principle they have studied is a review procedure, but it is also an essential part of the total learning experience. T.M.R.

RHODES SCHOLARSHIPS. The Rhodes Scholarships, established under the will of Cecil John Rhodes, the South African statesman and millionaire who died in 1902, were put into operation in 1904. The scheme provides for scholars from the United States, the British Dominions, and Germany to study at the University of Oxford. Approximately half of all the scholarships are allotted to the United States; there are for this country thirty-two appointments each year. The stipend is £400 per year; a scholar is appointed for two years in the first instance, but the

term may be, and usually is, extended for a third year. The selection of American Scholars is supervised by Dr. Frank Aydelotte, Director of the Institute for Advanced Study, Princeton, New Jersey, who has acted since 1918 as American Secretary to the Rhodes Trustees. Elections were suspended in 1939 for the duration of the war.

For the purpose of selecting Rhodes Scholars the country is divided into eight districts of six states each. There is a competition each year in every state. Each State Committee of Selection may choose not more than two candidates to appear before the District Committee. From the twelve men so nominated the District Committee selects four to represent their states at Oxford.

Candidates must not be younger than 19 nor older than 25, and must have completed the sophomore year in some recognized American college or university. In practice most Rhodes Scholars have received the A.B. degree before appointment. There is no requirement as to the subjects which a candidate must have studied and no restriction upon a Rhodes Scholar's choice of studies at Oxford.

There are about 1100 ex-Rhodes Scholars now living in the United States; they reside in every part of the country and follow a wide variety of occupations. The largest numbers are engaged in education, law, business, journalism (including radio broadcasting), government service, and the armed forces. American Rhodes Scholars have been notably successful in their different careers; many of them occupy positions of national importance; and the prestige of the Rhodes Scholarships has influenced the organization of reciprocal schemes bringing Englishmen to study in the universities of the United States. The purpose announced by Rhodes in establishing his system of scholarships was to ensure the peace of the world by bringing about closer understanding between young men of Great Britain and the British Dominions and those of the United States and Germany. If one takes the short view, it is clear that this purpose has not been fulfilled since the two greatest wars in history have been fought

since the Rhodes Scholarships were founded. But Rhodes did not take short views. In various letters he sets the period of a century or even two centuries as the time needed to give his Scholarships their full influence and effect. It will remain for the historian at the end of some such period to say the final word as to the truth of Rhodes' vision and the influence of his generosity upon the history of the modern world. ROLLINS COLLEGE PROGRAM. For forty years prior to 1925, Rollins had been a small college of high scholastic rank serving largely ambitious Florida youths in search of education. It had been founded by the same Pilgrim group which had established most of the New England colleges and pioneered in many of the Western private education institutions. It was thus well born.

Like most colleges, it had fixed traditions of instruction based on the lecture and quiz method. Under this system, learning has been largely an act of memory. The instructor was the active party to the process while the student took notes and gave back the information in the examination.

As a matter of fact, people are educated by their own mental activity and not by that of

the instructor. It was on this belief that the Rollins Conference Plan of teaching, suggested by President Hamilton Holt, was based. By it the student is given the opportunity to take a larger and more active part in his own education. Every device is used to induce students to ask questions—to quiz the instructor. In this way the process of education becomes a joint adventure of teacher and student.

Classes are limited to twenty, to make possible a close, friendly relationship between professor and student. Frequent conferences and tests are held, making the final written examination unnecessary. Conferences are of two types: the group conference which takes the form of class discussions, and the individual conference, scheduled outside of class time, which functions as a tutorial.

Rollins believes that one of the pressing problems of our colleges is to discover and develop a technique for such contagious education. The world struggle has only emphasized the need to humanize college training, to develop the initiative which was a dominant characteristic of the early American way of living and achieving.

The Conference Plan is as old as the streets of Athens in the days of Socrates. Rollins, we believe, was the first institution in the United States to transfer all its teaching to this informal Conference Plan. The Plan is not a "system" of instruction, it is rather an educational ideal—a common goal toward which the faculty and students of Rollins have made steady and hopeful progress. It is not a panacea but a fresh point of view. It is the Socratic method brought down to date.

Because the Conference Plan is not a system it offers the instructor wide liberty depending on his subject. It also prevents his becoming dogmatic.

Now after 17 years the Conference Plan is an established tradition at Rollins. Its young graduates acquit themselves creditably in their jobs whether in business, teaching, or in the graduate schools of leading universities. They have initiative, self reliance and an achieving dynamic. Judged by both tangible and intangible results, the Conference Plan has greatly stimulated the large majority of Rollins students to become active agents in their own education, both while undergraduates and after graduation. It has served to

humanize education, and develop something of the spirit of adventure.

A second feature of the Rollins educational program has to do with the individualized curriculum. The Conference Plan individualizes the method of instruction. The individualized curriculum is an attempt to build a student's program around his capacities, talents and real needs. These capacities and needs are discovered as a result of three months of careful study, implemented by the use of nationally-standardized objective tests, frequent individual conferences, and a careful examination of his life before he came to Rollins. Then, with his cooperation, a plan of study is mapped out which seems best to fit his individual needs. Thus the student's work is individualized both in method and content, and it is clearly shown that all of the work he does in college is a means to an end of developing in him good judgment, the ability to think clearly, and a sound set of values.

The student body is divided into an Upper and Lower Division instead of the usual four-year classes. The arrangement of the curriculum is such that the emphasis is placed upon generalization in the Lower Division, and upon specialization in the Upper Division.

"Rollins Housing Plan" has been developed to assist in what President Hamilton Holt likes to call "an Experiment in Common Sense Education." The eighteen new buildings erected during President Holt's administration are all in colorful Mediterranean architecture.

Rollins is distinctly a college of cultural arts with notable departments of Music, Art, and Drama. Its vested choir of fifty student voices provides the music each Sunday for the Knowles Memorial Chapel. The annual Bach Festival with its chorus of 125 voices is also held in the Chapel.

The Department of Drama functions in the modern Annie Russell Theatre, and also in the Fred Stone Laboratory Theatre where it produces one-act plays written, directed and acted by the students.

The Department of Art in addition to its extensive Art Library, its studios for painting, sculpture, and the applied arts, now has the new Morse Gallery of Art for its own and visiting exhibitions.

The Rollins educational program aims to

develop the whole individual, to prepare him to take a place of leadership in whatever vocation he enters, and to accomplish this with as much freedom as is consistent with high standards of scholarship. (See LIBERAL ARTS COLLEGE.)

E.O.G.

ROMAN CATHOLIC EDUCATION.

Catholic education provides for the education of the whole man, "soul united to body in unity of nature, with all his faculties, natural and supernatural, such as right reason and revelation show him to be." The Catholic theory is that the effects of original sin—weakness of will and disorderly inclinations—must be corrected and good habits must be developed. This cannot be done by relying solely on the powers of human nature. The mind must be enlightened and the will strengthened by supernatural truth and the grace of God. This is the same as saying that Catholic philosophy of education is the philosophy of the supernatural; that is, it has not only a philosophical but a decidedly positive theological basis. The late Monsignor Edward A. Pace, at one time Vice-Rector of the Catholic University of America, expressed it rather well when he said: "Education may be defined as that form of social activity whereby, under the direction of mature minds and by the use of adequate means, the physical, intellectual, and moral powers of the immature being are so developed as to prepare him for the accomplishment of his life-work here and for the attainment of his eternal destiny." The student is to be prepared for life here and hereafter. "For precisely this reason, Christian education takes in the whole aggregate of human life, physical and spiritual, intellectual and moral, individual, domestic and social, not with a view of reducing it in any way, but in order to elevate, regulate and perfect it, in accordance with the example and teaching of Christ."³ In order to achieve the ends of Christian education, it is necessary that the entire program be dominated by the Christian spirit, so that religion may be "the foundation and crown of the youth's entire training at every level of instruction."

Elementary Schools. From its very beginning the Catholic Church in America has held to the belief that secular and religious instruction may be dissociated only with grave danger to faith and morals. The Third

ROMAN CATHOLIC EDUCATION

Plenary Council of Baltimore, which convened in 1884, devoted one-fourth of its decrees to various aspects of education. The legislation was definite in character and is still in force. It required a school to be built in each parish within two years, and compelled Catholic parents to send their children to parochial schools. Only the Bishop of the diocese could permit a Catholic parent to send his child to a public school. The decrees of the Third Plenary Council have been taken as authoritative and final and have been complied with within the limits set by the economic resources of American Catholics. The Catholic parent is also obliged by Canon Law, under pain of mortal sin, to patronize the Catholic school. The teachings of the Church on parental responsibility are expressed quite clearly and forcibly in the encyclical letter of Pius XI, *Christian Education of Youth*: "For the mere fact that a school gives some religious instruction (often extremely stunted), does not bring it into accord with the rights of the Church and of the Christian family, or make it a fit place for Catholic students."

In many instances, during the early period of development, pastors served as teachers of secular as well as religious subjects. Lay assistants helped to extend the offerings and in time formal school organization was possible. The teaching at the elementary level was often cared for in the early days by priests or lay teachers holding degrees from European universities. Religious intolerance and language handicaps compelled the Hierarchy, especially during the high tide of immigration, to think in terms of "a school beside every church." Just as in the early days the missionary followed the explorer, so in a later period the teacher followed the missionary, especially after the Religious Communities of Europe turned to the New World to find greater opportunities of service. The leadership of the Hierarchy, the zeal of the immigrant, and the devotion of the teaching Religious made the rapid multiplication of parochial schools possible.

The Third Plenary Council decrees influenced the growth of parochial schools, since many Catholics were dissatisfied with public schools and needed only such counsel to undertake the task of organizing a separate school system. Burns and Kohlbrenner show

that in 1883, the year preceding the Baltimore Council, there were 6,241 churches and 2,491 schools; that is, forty per cent of the churches reported schools. By 1933, the numbers had grown to 12,537 and 7,462 respectively, showing that sixty per cent of the parishes offered education at the elementary level. While this represents a twenty per cent increase during the fifty-year period (1883-1933) in the number of parishes with schools, it falls far short of the ideal set by the Baltimore Council—a parochial school near each church. Poverty, indifference, widely scattered Catholic groups and the shortage of religious teachers may be cited as some of the reasons for inability to achieve the ideal.

The elementary division of the Catholic school system includes three types of schools: parochial, private and institutional. The parochial school is controlled by a parish; a private school, by a religious order; and an institutional school, by a diocese, a religious order or a private foundation. Of the 7,944 Catholic elementary schools, 7,056 are parochial; 559, private; 329, institutional. Parochial schools are now functioning in every State and in each of the 112 dioceses. Episcopal jurisdictions, bearing the names of American cities, provide extensive facilities such as: Chicago, 398; Philadelphia, 334; New York, 281; Pittsburgh, 229; St. Louis, 222; Brooklyn, 216; Milwaukee, 200. The schools in most jurisdictions are administered by a school board and a diocesan superintendent of schools empowered to appoint teachers, approve the curriculum, supervise instruction, prepare reports, direct building programs, and promote public relations. The superintendent and the board are directly responsible to the bishop of the diocese, who in turn is entirely free to adopt policies and practices which fit the peculiar needs of the schools of his jurisdiction. In other words, each diocese is autonomous since there is no national head of the Catholic school system. The unifying principle is the philosophy of education to which all subscribe, since it promotes a common belief in the efficacy of religious instruction, obedience to episcopal authority, and sound principles and methods. This is especially evident in the uniformity in policy and practice characteristic of the 139 Religious Orders which supply the 50,876 sisters required to care for the instruction of 2,035,182 pupils in 7,944 elementary schools.

margins. The sheet is ruled horizontally and vertically. At the proper intersections tallies are made from the pupils' choices in their preliminary registration. This procedure is time-consuming, but can be done by the clerical staff. The purpose of the sheet is to show at a glance what subjects will conflict with one another and the number of conflicts between any two subjects. Thus the scheduler, in his use of the schedule board, can determine from the conflict sheet what subjects it is unwise to plot in the same period of the day. This procedure will not remove all conflicts, but the number can be lessened. The three most general plans of building the daily schedule are the *block*, *mosaic*, and *combination methods*. The block method may be used where there are a sufficient number of pupils taking the same combination of subjects to provide for one or more sections of the various subjects. Such subjects may be omitted from the conflict-sheet tabulations and immediately inserted in the master schedule. The mosaic method involves the shifting of the cards or blocks on the master schedule to avoid the conflicts evident in the conflict sheet, and must be used for those pupils whose registrations make it impossible to use the block method. The combination method is the one generally used and, as its name implies, is a combination of the block and mosaic methods. In all these methods a certain amount of trial-and-error must be employed, although practice in schedule-making will tend to reduce it. The high-school principal will soon learn by experience certain short cuts in his work.

A few large schools make use of business machines such as the *Hollerith* for sorting and counting cards punched with the data from the pupils' preliminary registrations. The price of this equipment, however, is prohibitive for most schools. (See PROGRAM, W.R.F.F. DAILY.)

following year for American Literature. This is an example of both combination and yearly alternation.

To facilitate schedule-making, it is recommended that high-school principals, especially beginners, secure copies of former daily schedules of their schools and as much information as possible concerning the items already enumerated herein.

There are two general practices in schedule making, which are diametrically opposed to each other: (1) having pupils register from a more or less arbitrarily prearranged schedule, which is often the same in a given school, year after year, and (2) conducting a preliminary registration, or choice of subjects, and then making the schedule in terms of the pupils' choices. While the first method is more convenient administratively, it is generally considered undemocratic and poor administrative policy. The second method is the one recommended and followed by the better school administrators.

The preliminary registration should be made several weeks before the end of the first semester or the end of the school year. It is especially during this preliminary registration that the school should practice effective pupil guidance. Many school administrators require that the pupils' choice-of-subject blanks be signed by the parents.

Largely upon the basis of this preliminary registration and with other related facts in mind, the administrator sets himself to the task of preparing the daily schedule. There are at least two helpful mechanical aids that he can utilize. One of these is the *schedule board*, the form and size of which vary according to the needs and preferences of each school. The names of the various teachers, arranged alphabetically as a group or by department, are placed along one margin. The daily periods are placed in sequence along the other margin. Spaces or pockets are provided for the various proposed classes and activities sections. For these spaces or pockets there are prepared small movable cards or blocks having on them the names or sections of the different classes or activities. These can be shifted about on the schedule board to produce the best organization.

The second mechanical aid is the *conflict sheet*, which has the various subjects or activities listed in the same order on both

In addition, there are 1,142 priests and brothers and 3,643 lay teachers (1940).

Secondary Schools.

In the early part of the 19th century, Catholic secondary education for boys was available under the auspices of the Jesuits in Washington, St. Louis, and St. Mary, Kentucky. Various Religious Orders were offering secondary education for boys in some sixty colleges at the close of the Civil War. Nuns were caring for girls in approximately 200 academies by 1860. The intense popular interest in public secondary education, characteristic of the latter part of the 19th century, was paralleled by a concerted effort to extend Catholic secondary school facilities. American Bishops urged pastors and people to extend parochial education upward so as to lengthen the period of instruction under Catholic auspices. Parochial high schools soon developed and by 1915 more than 250 were in operation, mostly along the Eastern seaboard. Certain weaknesses inherent in this type of school, such as small enrolment, limited curriculum, inadequate library and laboratory facilities, etc., were soon remedied by the establishment of the central or diocesan high school. This type draws from many parishes, sometimes as high as fifty contributing to its support. The parochial high school is supported by the parish or by tuition fees. The central high school receives its chief support from the diocese in which it is located or from the parishes of which its students are members. In some instances, a nominal tuition fee is charged. The academy depends solely upon tuition fees. A fourth type of secondary school, the institutional, is usually operated by orphanage officials to provide some additional education beyond the elementary grades. There are 1,021 parochial high schools. There are only 10 institutional high schools. Of the 2,105 secondary schools, approximately 49 per cent are parochial high schools: 35 per cent, academies; 8 per cent, central. The traditional four-year program is offered by 1,622 schools. The usual curricula are classical, college-preparatory, academic, commercial, scientific, home economics, and general. Only 126 schools are operated on the 6-3-3 basis. (See EDUCATIONAL LADDER.) Ninety per cent of Catholic secondary schools are accredited. The services of 20,976 teachers are required to care for 361,123 students

Teacher-Education. The First and Second Plenary Councils of Baltimore considered the training of teachers of sufficient importance to make special mention of the problem, but it was not until the Third Council met, in 1884, that special provisions were made for extending the teacher-training program of the Church. The Third Council hoped to improve teaching through the establishment of Diocesan Examining Boards which would issue certificates to candidates passing examinations covering content and methods. Full preservice preparation was held up as the desirable goal but only very few Communities were able to attain this objective. In time, due to the desire of Catholic teachers to secure State certificates, the stronger communities established teacher-training programs, providing at least two years of training before certification for the elementary school. The cost of such programs. In many cases, state normal schools and universities were used to supplement community teacher-training facilities. Catholic institutions of higher learning established special programs in extension centers and during the summer months to care for the special needs of Catholic teachers working for State certificates. This movement gained full momentum shortly after World War I, especially in the East and Midwest, and has been largely responsible for the satisfactory standards in effect for Catholic teachers in service. Many communities now maintain their own normal schools and others conduct programs which have the approval of local Catholic colleges or universities. Five of the thirty-six normal schools and teachers colleges controlled by the Church are operated on a diocesan basis; that is, students from a number of Religious Orders are accepted for instruction. Fifteen of the institutions are conducted only for members of the communities controlling them, but some of the normal schools of the larger Religious Communities accept Sisters or Brothers from other groups who wish to satisfy requirements for certificates. Twenty-nine of the thirty-six teachers colleges and normal schools are accredited by accrediting agencies and three

(157,583 boys; 203,540 girls). Religious teachers account for 83.5 per cent and lay teachers, 16.5 per cent of the total number employed (1940).

found between school achievement and mental age are not very high, it has become customary to expect every child to "live up to his intelligence" in subject-matter achievement. This means that we expect him to reach a standard of achievement corresponding to the norm or average for his mental age. The concepts of *educational quotient* and *accomplishment ratio* have been introduced to describe whether the child does maintain such a level of achievement. (See EDUCATIONAL AGE.)

However, when correlations between intelligence and achievement in a particular subject are $+0.60$ and lower, accomplishment ratios will show a wide range both above and below 100. It is not fair, therefore, to expect all children to reach the mean school achievement for their mental age. Such an expectation signifies a belief that if all the children were properly motivated, they would all reach at least the level of achievement which is at present the average for their mental age. There is not enough justification for such an assumption. It is true that with better teaching the achievement norms for each age might be raised considerably, so considerably that the pupil who scores farthest below the norm at that time makes as high a score as the present average. However, if such an improvement were brought about, it would not necessarily mean that the range of achievement at any mental age level would decrease. The new norms would be higher but there might be the same number of E.Q.'s that did not correspond with the I.Q.'s. While better teaching should be expected to improve achievement, it would not follow that the correlation between intelligence and school achievement would be raised. However, it is important to bear in mind that even if one believes that the quality of a person's intelligence changes little throughout life, the fact that so many types of achievement have so low a correlation with intelligence means that there are other factors, many of them open to deliberate change, which also affect the standard of achievement.

Correlations between school achievement and intelligence are lower in high school than in the elementary school, and still lower in college. The decrease in the correlation with the level of schooling does not mean that intelligence counts for less at higher levels of

States to various European countries, and from one European or South American country to another. The Carnegie Corporation has likewise, without establishing any single uniform scheme, supported a large number of individuals whose plans made it necessary for them to go from one country to another for study and research.

The Institute of International Education, which administers the American Field Service Fellowships to France, supervises also a large number of appointments open to foreign students who wish to study in the United States or to American students who wish to study in some foreign country. Many of these fellowships are supported by small funds; others are individual exchanges. There are some twenty-five or thirty countries involved in these exchanges and the total number of students going in one direction or the other has in recent years varied between 6,000 and 9,000. (See also RHODES SCHOLARSHIPS.)

SCHOLASTIC ABILITY. Scholastic ability, as distinct from scholastic aptitude, indicates what can actually be achieved in school work, while the latter signifies what could be acquired with proper motivation and training. Theoretically, scholastic aptitude for all but the manual skills is supposed to be very closely correlated with intelligence. Actually, correlations between school achievement and I. Q. or mental age have not been found to be high. These correlations vary depending on the particular tests used, the particular subject-matter tested, and the particular groups tested. For example, correlations ranging from $+0.50$ to $+0.90$ have been found for different reading tests and intelligence. On the whole, the more verbal and abstract the subject-matter (e.g. reading and arithmetic reasoning), the higher the correlation with intelligence. The more concrete the task, the more it can be learned by rote, the more manual in nature (e.g. arithmetic computation and handwriting), the lower is the correlation with intelligence. One study found that among the same group of children the correlation between intelligence and the understanding of arithmetic was $+0.60$, while that of intelligence and arithmetic computation was $+0.35$, and that of intelligence and handwriting was only $+0.21$.

In spite of the fact that the correlations

ROMAN CATHOLIC EDUCATION

others are recognized by the Catholic University of America. Approximately 1,000 teachers care for 8,500 students. About sixty per cent of the students attend only during the summer session (1940). The programs of these institutions closely parallel the offerings of state teachers' colleges. Provision is made, of course, for instruction in the content and methods of religion, Catholic philosophy, church history, and character education. The entire program is based on the Catholic philosophy of education.

Seminaries. Seminaries for training candidates for the priesthood are maintained by Religious Orders and Dioceses. The preparatory or minor seminary offers six years of training, two of which are at the college level—usually in the classics. It differs from the usual high school and junior college set up in that only students who wish to study for the sacred ministry are accepted. The principle of segregation recognizes the directive of the Third Plenary Council of Baltimore that candidates for the priesthood must observe certain regulations governing discipline, religious instruction and the program of studies. The entrance age is usually about 14. Eighteen of the eighty-three preparatory seminaries are controlled by diocesan clergy; sixty-five, by Religious Orders. Thirty-nine institutions train only members of Religious Orders; twenty-three train secular or diocesan priests, and twenty-one prepare students drawn from both groups. The instructional staffs include 750 religious order priests, 310 diocesan priests, and seventy lay instructors. Of the total number of 9,262 students, 3,266 are enrolled in college courses and 6,426 in the high school departments (1940).

The major or theological seminary provides instruction in the Sacred Sciences as prescribed by Canon Law. Theological studies must be preceded by two years of philosophy, sometimes taken in the preparatory seminary. Four years are given to the study of theology. There are seven major seminaries which have been in existence more than one hundred years, the largest and oldest, St. Mary's Seminary, Baltimore, having been founded in 1791. Of the ninety-eight major seminaries, fifty-nine train members of Religious Orders, twenty-five train diocesan or secular priests, and twelve prepare students drawn from both groups. Seventy-nine institutions, however,

are controlled by Religious Orders, such as the Sulpicians, Jesuits, Vincentians, Dominicans, Benedictines, Passionists, Franciscans, etc. They generally care for students drawn from a given province. A few care for students on a national scale. A seminary which trains candidates for the secular or diocesan clergy may be diocesan, inter-diocesan, provincial or pontifical. The diocesan seminary is controlled by the Bishop of the diocese, the inter-diocesan by one or more members of the Hierarchy, the provincial by all the Bishops of an ecclesiastical province, and the pontifical by the Holy Father. Most of the seminaries which train secular priests are diocesan or inter-diocesan. Funds for support are secured from tuition fees, bequests, and diocesan collections. The religious order seminaries are supported by the Orders, Congregations, or Societies controlling them. Approximately three-quarters of the 1,400 major seminary teachers are members of Religious Orders. Of the 8,000 students, approximately fifty-five per cent are training for the diocesan or secular clergy (1940). It is evident that the training of students for the priesthood is the special duty of members of the Religious Orders.

Colleges and Universities. In the early days, because of conditions which also influenced the development of non-sectarian institutions, little distinction was made between a college and a secondary school. Of the thirty-eight Catholic institutions of higher learning in existence by 1850, eighteen were chartered and five were known as universities. After 1850 there was a great increase in the number of colleges for men, so that by 1866 there were sixty institutions offering instruction. By 1936 the number had increased to seventy-eight, distributed from coast to coast and from the Canadian border to the Gulf of Mexico. The Society of Jesus controls twenty-four of these institutions, the Benedictine Fathers, thirteen; secular or diocesan clergy, nine; Brothers of the Christian Schools, five; Congregation of the Mission, four; and Congregation of the Holy Cross, four. The remaining institutions, nineteen in number, are controlled by thirteen different Religious organizations.

The expansion of the programs of Catholic academies for girls was chiefly responsible for the inauguration of many college courses

Twenty-nine of the thirty-six teachers colleges and normal schools are accredited by accrediting agencies and three

ROMAN CATHOLIC EDUCATION

others are recognized by the Catholic University of America. Approximately 1,000 teachers care for 8,500 students. About sixty per cent of the students attend only during the summer session (1940). The programs of these institutions closely parallel the offerings of state teachers' colleges. Provision is made, of course, for instruction in the content and methods of religion, Catholic philosophy, church history, and character education. The entire program is based on the Catholic philosophy of education.

Seminaries. Seminaries for training candidates for the priesthood are maintained by Religious Orders and Dioceses. The preparatory or minor seminary offers six years of training, two of which are at the college level—usually in the classics. It differs from the usual high school and junior college setup in that only students who wish to study for the sacred ministry are accepted. The principle of segregation recognizes the directive of the Third Plenary Council of Baltimore that candidates for the priesthood must observe certain regulations governing discipline, religious instruction and the program of studies. The entrance age is usually about 14. Eighteen of the eighty-three preparatory seminaries are controlled by diocesan clergy; sixty-five, by Religious Orders. Thirty-nine institutions train only members of Religious Orders; twenty-three train secular or diocesan priests, and twenty-one prepare students drawn from both groups. The instructional staffs include 750 religious order priests, 310 diocesan priests, and seventy lay instructors. Of the total number of 9,262 students, 3,266 are enrolled in college courses and 6,426 in the high school departments (1940).

The major or theological seminary provides instruction in the Sacred Sciences as prescribed by Canon Law. Theological studies must be preceded by two years of philosophy, sometimes taken in the preparatory seminary. Four years are given to the study of theology. There are seven major seminaries which have been in existence more than one hundred years, the largest and oldest, St. Mary's Seminary, Baltimore, having been founded in 1791. Of the ninety-eight major seminaries, fifty-nine train members of Religious Orders, twenty-five train diocesan or secular priests, and twelve prepare students drawn from both groups. Seventy-nine institutions, however,

are controlled by Religious Orders, such as the Sulpicians, Jesuits, Vincentians, Dominicans, Benedictines, Passionists, Franciscans, etc. They generally care for students drawn from a given province. A few care for students on a national scale. A seminary which trains candidates for the secular or diocesan clergy may be diocesan, inter-diocesan, provincial or pontifical. The diocesan seminary is controlled by the Bishop of the diocese, the inter-diocesan by one or more members of the Hierarchy, the provincial by all the Bishops of an ecclesiastical province, and the pontifical by the Holy Father. Most of the seminaries which train secular priests are diocesan or inter-diocesan. Funds for support are secured from tuition fees, bequests, and diocesan collections. The religious order seminaries are supported by the Orders, Congregations, or Societies controlling them. Approximately three-quarters of the 1,400 major seminary teachers are members of Religious Orders. Of the 8,000 students, approximately fifty-five per cent are training for the diocesan or secular clergy (1940). It is evident that the training of students for the priesthood is the special duty of members of the Religious Orders.

Colleges and Universities. In the early days, because of conditions which also influenced the development of non-sectarian institutions, little distinction was made between a college and a secondary school. Of the thirty-eight Catholic institutions of higher learning in existence by 1850, eighteen were chartered and five were known as universities. After 1850 there was a great increase in the number of colleges for men, so that by 1866 there were sixty institutions offering instruction. By 1936 the number had increased to seventy-eight, distributed from coast to coast and from the Canadian border to the Gulf of Mexico. The Society of Jesus controls twenty-four of these institutions, the Benedictine Fathers, thirteen; secular or diocesan clergy, nine; Brothers of the Christian Schools, five; Congregation of the Mission, four; and Congregation of the Holy Cross, four. The remaining institutions, nineteen in number, are controlled by thirteen different Religious organizations.

The expansion of the programs of Catholic academies for girls was chiefly responsible for the inauguration of many college courses

RORSCHACH TEST

for women. In time, the offerings made a year or two of post-graduate work possible. Post-graduate students were admitted at St. Mary's Academy, Notre Dame, Indiana, as early as 1870. The first full four-year institution established was the College of Notre Dame of Maryland in 1895. Trinity College, Washington, D. C., founded in 1897 and opened in 1900, was the first to be founded as a complete college from the beginning. The rate of growth since the opening of the century has been quite rapid. Fourteen new institutions had been established by 1915. The number had increased to seventy-eight by 1926, and fourteen years later had reached the impressive total of 117.

Catholic higher education subscribes to the efficacy of prescribed studies and the theory of relative values in subject matter. The poor preparation of high school graduates has necessitated the gradual sacrifice of the classical ideal, so that today the classical languages, except in Jesuit institutions, are offered as electives. English, philosophy, science, and the social sciences account for the major portion of the instruction in liberal arts colleges for men. Religion is a required subject in every college. The curriculum of the women's college closely parallels that offered by the typical liberal arts college for men. Vocational subjects in late years have been given a place of greater prominence, such as secretarial studies, social service, education, and home economics. Art and music receive special attention in many institutions.

Fourteen institutions have university status, in the sense that they have a graduate school and an administrative officer responsible for the direction of graduate studies. They are as follows: Catholic University (Washington, D. C.); Creighton (Omaha); De Paul (Chicago); Detroit (Detroit); Duquesne (Pittsburgh); Fordham (New York); Georgetown (Washington, D. C.); Gonzaga (Spokane); Loyola (Chicago); Marquette (Milwaukee); Niagara (Niagara Falls); Notre Dame (South Bend); St. John's (Brooklyn); St. Louis (St. Louis). Not until the opening of the century did the university movement gain full momentum, six of the fourteen universities securing university charters since 1906. In nine of the universities, the professional students account for forty-three per cent of the total enrollment. More

than thirty-three per cent of the professional schools have been established since 1920. Of the professional schools conducted under Catholic auspices, 17 are schools of law; 15, business or commerce and finance; 9, nursing; 8, engineering; 7, dentistry; 6, education; 5, medicine and pharmacy; 3, social work or social service; 2, drama, music and journalism.

The total number of teachers in the 193 colleges and universities is 13,142. Of these, 6,525 or approximately 50 per cent are Religious and 6,617 or 50 per cent are lay. The total enrolment is 161,886. Of these, 47.3 per cent are men and 52.7 per cent, women.

RORSCHACH TEST. The Rorschach Test is a method of psychological analysis devised by a Swiss psychiatrist, Herman Rorschach (1882-1922), and refined and improved by the work of many of his followers. At the present writing, many psychologists consider it the best available method for the analysis of the structure of an individual's personality, while others are decidedly skeptical of the many claims made for the test.

The material consists of reproductions of ten standardized ink blots, some of which are colored. The subject is asked to tell what he sees in the blots, taking them one at a time. Great individual differences in reaction are found. The procedure is a "projective" one, in that the subject is presented with ambiguous, comparatively formless and meaningless material, and what he sees in the blots is a projection, or expression, of his own inner tendencies. It is different from most other

projective techniques in that the content of the description given by the subject is not the major criterion upon which the analysis of the responses is based.

Each response is scored in several ways: (1) for location, or the part of the blot used in the interpretation; (2) for determinants, or the qualities such as form, color, shading, and movement which may influence the interpretation; (3) for content, or the specific kind of thing seen; (4) for whole or detail responses, i.e., to what extent the subject interprets the blots as wholes or units, and to what extent he is concerned with parts as separate from the whole; and (5) for the commonness or variety of the responses (popularity or originality). Although scoring is to a large degree subjective, trained scorers usually agree very closely on the scoring for a whole record. The proper interpretation of a Rorschach record is a time-consuming and difficult task, requiring a thorough familiarity with clinical psychology as well as an extended period of training in the use of the test. The interpretation depends less on the number of responses of each kind than on the pattern of responses, and the balance among the various kinds of possible responses. An acquaintance with the typical "test profiles" of various clinical groups as reported in the research literature is essential.

The Rorschach test is being used at the present time mainly as a diagnostic instrument in psychological and psychiatric clinics and institutions, where it is often of value in making a differential diagnosis. Other uses are as an aid in vocational guidance and as a research instrument in making comparisons between clinically or culturally different groups. The standard method of administration is individual, the subject examining one card at a time and giving his responses orally. A method of group administration has been worked out recently in which the ink blots are reproduced on slides and projected onto a screen, with each subject writing his own responses. ROSENWALD FUND — See FOUNDATIONS, PHILANTHROPIC.

ROUSSEAU, JEAN J. (1712-1778).

Rousseau has been universally conceded to be an important figure in political philosophy, in the Romantic movement in literature, in child psychology, and in education. His educational significance was many-faceted, but the central core lay in his doctrine of *Naturalism* (q.v.).

The Naturalistic Conception of Education. The first half of the eighteenth century in European intellectual history was a period of rationalism. Voltaire, Diderot, and the Encyclopedists were its protagonists; rationalism—frigid, individualistic and aristocratic, was its test of the good, the true, and the beautiful.

Rousseau, writing in the second half of the century, strove to substitute for rationalism a set of values stressing faith in nature, and in the warmer, more deep-seated emotional processes. He gave "the first great boom to the human emotions."

It is probable that, like all perfervid reformers, Rousseau stated his naturalistic propositions with his tongue in his Genevan cheek. The balance between the claims of nature and of nurture needed to be righted; one way to accomplish this was to claim exclusive validity for "nature." The controversy between hereditarians and environmentalists, much more recent in educational history, illustrates the same proneness to hyperbole in trying to arrive at an acceptable mean.

The extreme naturalistic note is sounded in the opening sentence of Rousseau's *Emile*: "Everything is good as it comes from the hand of the author of nature; but everything degenerates in the hands of man."

From this premise, Rousseau draws several broad educational applications. The natural man is a doing, before he is a learning animal; hence early education according to nature should be without books and without didactic instruction. The senses should be trained in the presence of nature. The body should be toughened and inured, in which belief Rousseau was echoing the hardening process of Locke. In these, and like ways, education should be negative, which does not

mean that there should be no education, but means in Rousseau's paradox, that time should be gained by losing it.

Naturalism in its application to moral education led him to the theory of natural punishments; namely, the theory that the child should suffer the consequences of his own misdeeds without the positive intervention of adults. Vulnerable as this concept of moral education is—and commentators on Rousseau have been quick to attack it—it at least directed attention to the principle that personal resentment should be removed from all discipline, and that specific disciplinary measures should be selected and evaluated, wherever possible, in terms of cause and effect relation to acts.

Lines of Continuing Influence. Rousseau is one of those figures in whose case "contradiction's lightning shocks lose power." One of his major contributions has been to make the child and his nature the center of the educational process and not subject-matter as embalmed in school books. A second contribution has been to call attention again to the need for recognizing stages of maturation in child development, each with its own needs to be studied and understood. His own definition of these growth periods (birth to five, five to twelve, twelve to fifteen, fifteen to twenty) was undoubtedly too abrupt, but educational theory has never since lapsed into the dangerous assumption that a child of five is but a vest-pocket edition of a child of fifteen.

Rousseau's influence on France and by way of France on America was chiefly in the field of political philosophy. His influence on England was chiefly on the Romantic movement in literature. It was by way of Germanic Europe, through the work of Basedow and later *Philanthropinists* that his educational influence passed into the nineteenth century stream of the Psychological Movement of which Pestalozzi, Herbart, and Froebel (*qq.v.*) were the protagonists. ROUTINIZATION OF CLASSROOM ACTIVITIES—See CLASS MANAGEMENT.

RURAL EDUCATION. The education which takes place in schools located in areas populated by 2,500 persons or less. This is the definition agreed upon by the United States Office of Education statisticians, writers, and administrators. The number of schools, teachers, and children thus included is considerable. According to the 1940 Report of the United States Office of Education 90 per cent of the 256,000 graded schools and 78 per cent of the 18,000 high schools are rural; and 53 per cent of the 63,348 public school teachers are from rural areas. Moreover, the rural schools are small. Of the number of graded schools 138,542 were built for one-teacher and 24,412 for two-teacher schools. Of approximately 50,000 schools in the United States built for not more than six teachers 60 per cent of these were one-teacher rural schools, and 82 per cent of them were taught by one or two teachers.

In addition to the small two-and three-teacher schools, other types serving rural children are village, town, and consolidated schools. (See CONSOLIDATION OF SCHOOLS.) The latter represent an interesting and significant development in rural education and constitute an effort to meet the inherent problems present in small schools. The consolidation movement of small rural schools into larger administrative units began as early as 1869 in Massachusetts, and the movement spread gradually if unevenly throughout all the states. In 1915-16 there were 5,000 consolidated schools; in 1935-36 the number had increased to 17,531. In order to make the consolidation of schools effective it has sometimes been necessary to transport children over great distances. In 1915-16 there were 525,000 rural children transported to consolidated schools; in 1935-36 this number had been increased to over three millions.

Approximately one half of the total child population in the United States lives in rural areas, but this proportion does not hold for adults. Of every 100 adults in the total population 40 live in rural, 60 in urban areas. Thus rural areas with almost 20 per cent smaller total population have a group of children to educate equal in size to that of the cities. In 1934-35 there were approximately twenty-seven million children enrolled in all

the public schools in continental United States; 48.8 per cent of these attended rural schools, and 16.0 per cent, one- and two-teacher schools.

According to recent studies, the teachers in rural schools are characterized by youthfulness, femininity, and low professional education. Poor salaries and the consequent mobility of the teachers prevail. According to a 1933 national survey of the education of teachers the median rural teacher of a small school was described as follows:

"The typical white teacher in the one- and two-room country school in 1930-31 was a young woman, unmarried, about twenty-four years of age, of farm or village background. Her education consisted of four years of high school and one year or more of professional preparation somewhat directed to rural-school needs. The experience of this typical rural teacher was 4-6 years during which time she had taught in two different rural schools. Her median annual salary in the fall of 1930 was \$788, but during the year she received a salary reduction of 10 per cent. She worked eight months out of twelve, teaching twenty to twenty-five children through eight grades of elementary curriculum and performing, especially during the depression, a considerable number of community and welfare services as well."

Rural schools are usually administered by a district or county superintendent of schools appointed by local boards or, more frequently, elected directly by vote of the people, though there is a modern trend toward the selection of such administrative officers by special boards on the basis of qualifications for the office. The county or the district superintendent of schools is usually responsible for the supervision of rural schools as well as for their administration.

The curriculum used in the rural schools is similar to that used in the urban schools with the exception of certain adaptations to the environment in which the school is located. This is particularly true in the fields of science and the social studies. In the rural high schools emphasis is likely to be placed on agriculture and home economics. A few states have issued courses of study which adapt the organization of curriculum materials to the rural schools. These are New York, New Jersey, Montana, North Dakota, Pennsylvania,

and, to some extent, Indiana.

Teaching procedures in the rural schools are similar to those used in urban schools, except when the schools have fewer than three teachers. The chief differentiation here lies in the field of organization. Children in rural schools are not classified along strictly graded lines, but are assigned to flexible groups. Individual and small-group guidance is, then, characteristic of the best instruction in these schools. Further devices frequently used to meet the problems of the one teacher handling many grades are alternation of subjects, the combination of curriculum materials, and the teaching of all the children as one group in certain subjects, especially in music, health, and sometimes in science and the social studies.

Several points of difference between rural and city schools are significant. In the main these are (1) the differences in environment which not only affect child development but also tend to differentiate the curriculum of the school; (2) the organization of the rural school which makes impossible the assignment of a teacher to a grade; (3) the mobility of teachers, which makes the rural-school experience a kind of apprenticeship for urban areas; (4) the lack of materials in books and other tools for teaching; (5) the inadequate supervision provided by county or district superintendents of schools because of the heavy burden of their administrative duties. (See COUNTY SCHOOL SYSTEM; DISTRICT SCHOOL SYSTEM; ONE-ROOM SCHOOL.)

S

SABBATICAL LEAVE. For the purposes of study, travel, rest, and other means of self-improvement, teachers and others of the school staff are sometimes granted a leave of absence with or without pay for a period not exceeding one year. The usual practice is the granting of this leave of absence on a seven-year cycle of employment. Many school districts now grant such leaves to teachers, supervisors, and administrators.² In the great majority of school systems in the United States the sabbatical leave is without pay.

Campbell reports that the most commonly used system of sabbatical leave in institutions of higher education grants leave to teachers of professional rank.¹ It is sometimes explicitly stated, and usually assumed, that the leave may not be used to enter the services of other institutions nor to engage in other remunerative employment. Many institutions require that the professor file a bond that he will remain in the institution one or more years after the leave. It is the almost unanimous belief among administrators that the sabbatical leave is a desirable practice.¹

In 1937 the Pennsylvania legislature passed a law to the effect that public school teachers who had taught in first-class school districts for ten years were entitled to a leave of absence for such purposes as health, study, or travel. The person on leave received the difference between his salary and that of the substitute up to \$800 for a half year or \$1,600 for a full year.³ Thereafter a leave was to be allowed for each seven years of service. This act put into effect throughout the state many privileges that had hitherto been restricted to relatively large and progressive cities.

The New York City Teachers Guild has a sabbatical-leave program that may serve somewhat as suggestive of an ideal program of sabbatical leave for teachers in the public schools. (In New York City the teacher or

supervisor on sabbatical leave receives his usual salary less the cost of the substitute teacher. An elementary school teacher who has taught long enough to receive the maximum salary is paid a little more than \$2,000 a year while on leave, and a senior high school teacher on maximum salary receives approximately \$2,750 while on sabbatical leave. Practically all teachers who are eligible for sabbatical leave receive the maximum salary for their position. Up to October 6, 1942, members of the school clerical staff, library assistants, and laboratory assistants also were eligible for sabbatical leave.) The program of the New York City Teachers Guild recommends that:

1. The first sabbatical leave should be granted after seven years of service instead of ten. (A sabbatical leave of absence is for one school term.)
2. A teacher who has served for thirty or more years and has had fewer than three sabbatical leaves may apply for an additional leave or two consecutive leaves.
3. Every teacher should receive as many sabbatical leaves as he is entitled to by his years of service divided by seven.
4. If an applicant has received an unsatisfactory rating because of his health, that rating should not stand in the way of his being granted a sabbatical leave.
5. A teacher who has been on sabbatical leave for restoration of health, and who has not received his maximum salary shall be permitted to meet his alertness study requirements within the three-year period following the termination of the leave.
6. A sabbatical leave or two consecutive leaves may be granted to teachers who have had fourteen years of service, not only for the purposes of health or study but also for travel or rest.
7. A teacher who has not been in the service for a full five-year period be-

fore applying for a sabbatical leave shall be granted a leave if it is warranted by the total number of years of actual teaching service. To a limited extent credit should be granted for evening school service and substitute service.

(See LEAVE OF ABSENCE.)

SACCADIC MOVEMENTS—See **READING, EYE MOVEMENTS IN.**

SAFETY EDUCATION. Safety education is relatively new in the school curriculum. The reasons for this fact are varied. One, of prime importance, is that we have produced many devices and innovations, intended as benefits but possessing inherent dangers, much faster than we have perfected the techniques for meeting these dangers effectively. Various forms of high-speed transportation; the development of complex industrial machinery with emphasis on accelerated production; homes which now include a wider variety of conveniences but which, as in the case of numerous electrical devices, may also include greater potentialities for accident and fire—all these have appeared in a short span of years. Safety education is the attempt to overcome the lag between the appearance of such benefits and efficiency in their use.

It has been felt increasingly among thoughtful persons deeply concerned with this problem that our society has been paying too high a price for its apparent benefits. With the annual average loss of nearly 100,000 persons, including 34,000 killed in motor vehicle accidents, 32,000 in the home, 17,000 in occupations, and 15,000 in other public accidents; with 9,000,000 persons receiving disabling injuries in a single year; and with the annual economic loss alone computed conservatively at \$3,000,000,000, there can be

little doubt that here is a problem needing for its solution the best of our educational resources. World War I saw an acceleration in the initiation of safety programs, and World War II may well provide the final convincing proof that we have both an unnecessary and a largely avoidable depletion of human and material resources.

Definitions. Safety education is usually defined as that kind of education which teaches us to "avoid the common hazards of life that are avoidable and to face bravely those which cannot be avoided." (American Association of School Administrators, *Eighteenth Yearbook*, Safety Education, Chapter 1, 1940) Albert W. Whitney points out that "safety has a negative side, to be sure, but this is balanced by a positive side of equal significance. We are to be saved from something, but only in order to be saved for something else." Thus safety substitutes good adventures for bad. It tends to eliminate the dull, stupid accidents of life so that one can go on to the more interesting, purposeful, yet perhaps more dangerous, adventures. Safety education, therefore, attempts to provide for an ordered world. It shows how one can be master of his environment by being able to control many of the forces in the physical world that might tend to be hazardous. To illustrate: Fire can be very dangerous, but at the same time can be controlled. The individual who knows the common causes of fires, how they can be prevented and how extinguished, and who has developed good practices and attitudes toward fire hazards is much less likely to be involved in accidents resulting from fires. The educated person thereby knows of the various hazards and develops safe practices and attitudes with regard to them.

The School Program. Safety education is now generally accepted by school people and the public as a proper and necessary responsibility of the school. This was formally expressed in the *Eighteenth Yearbook* of the American Association of School Administrators. "It is the responsibility of the school to contribute as largely as it can to happy and useful living. If we confine our work to preparing children to do better those things which they will do anyway, we had better help them plan their accomplishment free from destructive encounters with pails of scalding

water, high tension wires, onrushing automobiles, and unwary pedestrians."

Safety instruction begins in the kindergarten and extends through the senior high school. It is also included in colleges, especially those concerned with the training of teachers, engineers, and others in safety services. Current practices reveal two major types of organization: (1) integration of safety education with many other school subjects and activities, and (2) safety education as a separate subject. Both methods are used and many schools use a combination of the two. In the elementary schools safety education is taught as a part of reading, the social studies, science, and health education.

In general, it has been found best to stress the accident hazards by seasons, such as fire-arms, fires, and home dangers in the autumn months; coasting and skating in the winter; swimming, water, play, and recreational hazards in the spring. Many schools feature one phase of safety each month; others build their program around the common activities of children, i.e., roller skating, coasting, kite flying, and the like.

In the high schools, safety has been taught for many years in connection with the social sciences and natural sciences, especially general science, biology, physics, chemistry, and community civics. The good chemistry teacher naturally emphasizes the dangers of chemicals used in the laboratory and in industry. Certainly, instruction that tends to prevent accidents and reduce property loss is of basic value. There is little doubt, for example, that fire-prevention lessons have contributed greatly to the reduction of preventable fires.

In the past there has been a tendency to overemphasize traffic safety at the expense of other less spectacular but nonetheless hazardous fields. The complete school program should include all fields of safety and should be set up following a study of the nature and frequency of accidents in the school and in the community. There has also been a tendency on the part of teachers to depend too much upon less valuable methods of instruction, such as the use of rules and regulations, slogans, and negative methods. It has been found that demonstrations, practice lessons, dramatizations, and visual lessons have much more value in actually establishing good practices and attitudes. Being informed about a

danger is not enough; one must develop the necessary habits, skills, and attitudes to meet or avoid that danger.

Classroom instruction is only one part of the school program, however. Co-curricular activities provide another important part. School safety patrols, traffic squads and courts are found in a large percentage of the schools. They are organized to protect children on their way to and from school, to direct traffic within the building, and to prevent accidents on the playground and in the gymnasium. Safety councils and such clubs as Swimming and Water Safety, Boy Scout, Rifle Practice, First Aid, Auto Mechanics, and Motor Clubs are organized to encourage safe practices and attitudes and to provide activities through which pupils can learn by doing. In addition the school assembly provides one of the best means of teaching safety through plays, pageants, motion pictures, sound film, slides, and demonstrations.

New Emphasis in the Secondary School Program. There are three important needs that were intensified after the outbreak of World War II. The first is preinduction driver education to prepare young people for the armed services. It has been found that one of four enlisted men is called upon to drive some type of motor vehicle in our mechanized army. In view of this, the U. S. Office of Education and the War Department have recommended that this instruction be given in the upper classes of the high schools. It has been demonstrated that such training not only helps shorten the time required for the Army to train personnel to drive its vehicles, but that such training helps prepare young people to meet the responsibilities of driving such civilian vehicles as trucks, buses, ambulances, and private passenger cars.

The second need is for more stress on safety instruction in school shops. Industry is calling for an ever-increasing number of workers. It has been found that accidents, fires, and other disasters cut deeply into manpower, resulting in delay on the production lines. Industrial accidents have become a form of sabotage in the national effort. Safety has therefore become a basic requirement in industry, and the schools can do much to build up proper attitudes and practices among the young people enrolled in our shops.

The third important need is for more home-safety and fire-prevention instruction. Indus-

ST. JOHN'S COLLEGE PROGRAM

try has found that there is more loss of time and production because of off-the-job accidents than accidents in the plant itself. Fires in the home, falls, burns and scalds, gas and electrical accidents, poisoning, and other types of home accidents result in altogether too many deaths and injuries. Instruction to prevent these accidents can be given in household arts, the school shops, and in general science and chemistry. Since accidents, fires, and other disasters rob us of so much manpower and material each year, everything that can be done by the schools to give safety instruction thereby tends to strengthen our national security.

Results of Safety Education. It is estimated that in the period between 1930 and 1940 more than twenty-five thousand child lives were saved, in addition to between seven hundred thousand and eight hundred thousand children saved from injury. No one can estimate the economic value of this saving or the reduction in property loss that has resulted. In the face of a steady rise in accidents involving adults, there has been a steady decline in those to school-age children.

There are many examples of cities that have established remarkable records in child accident prevention. It has been shown that a school system having a well-planned safety program can reduce its accidents 20 to 50 per cent. It is interesting to note that while water sports have more than doubled during the past decade, accidents involving children of school age have shown a marked decrease. The swimming and water-safety instruction given by the schools, camps, and other agencies, in cooperation with the American Red Cross, has been instrumental in effecting this reduction. There is no question but that safety education yields rich dividends in the actual saving of lives and in the reduction of preventable injuries. It is a discipline which must be assumed if we are not to be destroyed by our own creations.

ST. JOHN'S COLLEGE PROGRAM.

The St. John's Program, the liberal arts curriculum inaugurated by St. John's College, Annapolis, in 1937, is a four-year program leading to the Bachelor of Arts degree, required of all students in the College, and including no electives. Its purpose is to teach students to practise the liberal arts—the arts of reading, of writing, of speaking, of listening, of understanding, in short of manipulating successfully the complicated and subtle symbols, whether linguistic or mathematical, through which human thinking goes on and through which human action becomes thoughtful action. The curriculum is not intended to furnish professional or vocational training in any subject matter, although in order to carry out its own purpose, it incidentally furnishes the student with a considerable knowledge of many subject matters now taught in the elective system. It assumes that the best “pre-professional” training, regardless of the profession the student may choose, is a sound basic training in the liberal arts and a direct intellectual experience of the great minds of our civilization.

In order to achieve these purposes, the curriculum uses as mediums in which the student may learn to practise the liberal arts, the great books of our civilization, in all “fields” from Homer to the twentieth century. These are read in English translation by the student and discussed two evenings a week in a “seminar” of twenty students under the guidance of two instructors. Perhaps the best model of the seminar technique St. John's aims at is to be found in the question-and-answer, the give and take of a Platonic dialogue. There is no lecturing in the seminar, no reciting, no quizzing. Supplementing the seminar the student attends five tutorials a week in mathematics, where in a class of not more than ten he recites, goes to the blackboard, and irons out his personal difficulties. He attends five similar tutorials a week in language, where he analyzes, interprets, criticizes and composes. For the first four trimesters, he studies Greek, translates, paraphrases; for the rest of his four years,

ST. JOHN'S COLLEGE PROGRAM

his language tutorial is chiefly a matter of closer reading of the great books than is attempted in the seminar. One afternoon a week in his first two years, and two afternoons a week in his third and fourth year, he works in a laboratory in a section of twenty, handling experiments in physics, chemistry, and biology. One evening each week he listens to a formal lecture of an hour and a half, delivered to the entire college, and followed by a discussion and heckling period of indefinite length. This weekly regime is followed for four years.

The student stands a half hour oral examination each trimester, followed by a "don-rag" a week later, of fifteen minutes, during which he listens to each of his instructors report in detail on his progress and deficiencies. At the end of each of his first three years he writes an essay on a topic chosen from a posted list or on one of his own choice. At the beginning of his third year, he takes written and oral examinations on the work he has covered. If he passes, he is admitted to candidacy for the degree and during his fourth year gets a month off in which to write a dissertation. This dissertation, which is not expected to show original research but a genuine capacity to say something important and significant, he defends in a formal, one-hour, public oral examination.

The St. John's College student body represents a fair cross-section of American high-school graduates, in terms of intellectual ability. It is also heterogeneous socially, economically, and geographically. Its graduates represent the same range of later occupations that the colleges of other colleges do, professional schools included. Beginning in 1939, intercollegiate competition was dropped from the College athletic system and participation in voluntary intra-mural sports greatly expanded. Beginning in 1942, students were admitted from the second year of high school, with excellent results.

A list of the great books around which the curriculum is organized follows. This list undergoes constant revision in the light of teaching experience:

A LIST OF GREAT BOOKS

In Chronological Order

Homer: *Iliad* and *Odyssey*
Æschylus: *Oresteia*

Herodotus: *History*
Sophocles: *Ædipus Rex*
Hippocrates: *Ancient Medicine and Airs, Waters, and Places*
Euripides: *Medea*
Thucydides: *History of the Peloponnesian War*
Aristophanes: *Frogs, Clouds, Birds*
Aristarchus: *On the Sizes and Distances of the Sun and Moon*
Plato: *Dialogues*
Aristotle: *Organon, Poetics, Physics, Politics*
Archimedes: *Selected Works*
Euclid: *Elements*
Apollonius: *Conics*
Cicero: *On Duties*
Lucretius: *On the Nature of Things*
Virgil: *Æneid*
The Bible
Epictetus: *Moral Discourses*
Nicomachus: *Introduction to Arithmetic*
Plutarch: *Lives*
Tacitus: *The History*
Ptolemy: *Mathematical Composition*
Lucian: *True History*
Galen: *On the Natural Faculties*
Plotinus: *Enneads*
Augustine: *Confessions, On Music, Concerning the Teacher*
Justinian: *Institutes*
Scotus Erigena: *On the Division of Nature*
Song of Roland
Saga of Burnt Njal
Grosseteste: *On light*
Bonaventure: *On the Reduction of the Arts to Theology*
Aquinas: *On Being and Essence, Treatise on God, Treatise on Man*
Dante: *Divine Comedy*
Chaucer: *Canterbury Tales*
Villon: *Le Grand Testament*
Oresme: *On the Breadths of Forms*
Pico della Mirandola: *On the Dignity of Man*
Leonardo: *Notë Books*
Machiavelli: *The Prince*
Erasmus: *In Praise of Folly*
Rabelais: *Gargantua*
Copernicus: *On the Revolutions of the Circles*
Calvin: *Institutes*
Montaigne: *Essays*
Gilbert: *On the Loadstone*
Cervantes: *Don Quixote*
Shakespeare: *Henry IV, Hamlet, King Lear, Macbeth, Tempest*
Francis Bacon: *Novum Organum*
Kepler: *Epitome of Astronomy*
Harvey: *On the Motion of the Heart*
Corneille: *Le Cid*
Galileo: *Two New Sciences*
Descartes: *Geometry, Discourse on Method, Meditations*
Hobbes: *Leviathan*
Boyle: *Sceptical Chymist*
Molière: *Tartuffe*
Pascal: *Pensées*
Milton: *Paradise Lost*
Racine: *Phèdre*
Grotius: *Law of War and Peace*

ST. LOUIS PLAN — SAMPLING

Spinoza: *Ethics*
 Newton: *Principia Mathematica*
 Locke: *Second Treatise on Civil Government*
 Huygens: *Treatise on Light*
 Berkeley: *Dialogues between Hylas and Philonous*
 Leibniz: *Discourse on Metaphysics, Monadology*
 Vico: *Scienza Nuova*
 Swift: *Gulliver's Travels*
 Hume: *Treatise of Human Nature*
 Montesquieu: *Spirit of Laws*
 Fielding: *Tom Jones*
 Voltaire: *Candide, Mircromegas*
 Rousseau: *Social Contract*
 Gibbon: *Decline and Fall of the Roman Empire*
 Smith: *Wealth of Nations*
 Kant: *Critique of Pure Reason*
Constitution of the United States
Federalist Papers
 Bentham: *Principles of Morals and Legislation*
 Lavoisier: *Treatise on Chemistry*
 Malthus: *Principles of Population*
 Dalton: *A New System of Chemical Philosophy*
 Hegel: *Science of Logic*
 Coleridge: *Biographia Literaria*
 Fourier: *Analytical Theory of Heat*
 Goethe: *Faust*
 Lobachevski: *Theory of Parallels*
 Balzac: *Père Goriot*
 Faraday: *Experimental Researches in Electricity*
 Schopenhauer: *World as Will and Idea*
 Peacock: *Treatise on Algebra*
 Thackeray: *Henry Esmond*
 Dickens: *Bleak House*
 Boole: *Laws of Thought*
 Virchow: *Cellular Pathology*
 Mill: *On Liberty*
 Darwin: *Origin of Species*
 Bernard: *Introduction to Experimental Medicine*
 Mendel: *Experiments in Plant Hybridization*
 Hamilton: *Quaternions*
 Riemann: *Hypotheses of Geometry*
 Dostoevski: *The Possessed*
 Marx: *Capital*
 Tolstoi: *War and Peace*
 Dedekind: *Essays on Numbers*
 Maxwell: *Electricity and Magnetism*
 Flaubert: *Bouvard and Pécuchet*
 Ibsen: *Ghosts, Rosmersholm*
 Galton: *Enquiries into the Human Mind and its Faculties*
 Joule: *Scientific Papers*
 Clifford: *Common Sense of the Exact Sciences*
 James: *Principles of Psychology*
 Freud: *Studies in Hysteria*
 Cantor: *Transfinite Numbers*
 Hilbert: *Foundations of Geometry*
 Poincaré: *Science and Hypothesis*
 Russell: *Principles of Mathematics*
 Veblen and Young: *Projective Geometry*

SAMPLING. In most branches of study and research, it is impossible to study all the cases or individuals. The total *population*, or *universe*, as it is called, can rarely be studied because it is physically impossible to do so. The numbers and amounts are usually much too large.

Consequently it is necessary to study a sample of the total. The sample should have the characteristics of the population, in other words, it should be like the population which it represents. The necessity of having the sample typical of the total is obvious, when on the basis of the sample, general conclusions are drawn that are intended to be applicable to the whole population. If the sample is not a true or accurate sample, then the conclusions or generalizations made are misleading because they are drawn from data which are not representative of the total. Thus, the results of an experiment conducted with 100 thirteen-year-old boys may be interpreted as applying to all thirteen-year-old boys only if the 100 boys who were studied are representative of all boys that age.

A few examples illustrate what is meant. For example, when the elevator man grades a truckload of grain brought to the elevator, he takes small amounts of grain from the load at various times while it is emptying into the bin. By taking small measures of grain from the stream of grain emptying from the truck from the time the grain begins to flow until the truck is emptied, the elevator man aims to have a sample which accurately represents the entire load. The sample is tested for weight, moisture, and amount of foul material. On the basis of the tests, the load of grain is rated and the likelihood is that this method is accurate.

In another instance the investigator may have a million or more records. This is the situation as it pertains to records for the soldiers conscripted for World War II. There are several million records including psychological, and social data. Studies can be made of these records to find the variability and central tendency of several traits and characteristics. Even though we now have machines that can handle punched cards very

rapidly, still it is very probable that only a sample will be used rather than the whole supply or population. Possibly every tenth, hundredth, or five hundredth record will be satisfactory. The sample should be large enough to be highly reliable but not so large that an inordinate amount of work is required to make statistical analyses.

Random Sample. A *random sample* is a limited group selected from a larger population or universe on a purely chance basis. Two conditions which must be met in the selection of a random sample are that every individual in the population must have an equal chance of being chosen, and that all choices must be independent, i.e., one choice should not affect any subsequent choice. A random sample is not necessarily representative but any non-representativeness is due to the operation of chance. As the random group increases in size with reference to the larger group, the greater becomes the likelihood of its being truly representative. Mechanical methods of selection, such as drawing lots, selecting names at arbitrarily specified regular intervals from a list, and using tables of random numbers may be expected to produce a random sample. The war draft, the Irish Sweepstakes, and the various "Bingo" games all illustrate the principles of random sampling. We virtually never have random samples in educational research. In some instances it is not satisfactory to try to obtain a sample by random selection, but it may be satisfactory to select a sample through careful selection of a representative sample.

In conducting straw votes, for example, it is desirable to use as small a sample as possible, but to have one that will yield true and accurate results. It is essential to consider the factors which influence people in their voting. Usually economic or vocational classification is the best. Thus the sample should have proportional parts which are characteristic of the whole population. If 5 per cent of the adult population are in the professions, then 5 per cent of the sample should belong to the professions. Experience has indicated that samples drawn by this method for conducting straw polls have proved satisfactory. Factors such as geographical location, religion, and nationality should also be taken in account on certain issues or questions. It is essential in trying to obtain a representative

sample to consider only the factors which exercise influence.

How can one tell whether the sample is representative of the population or universe? One never can be sure because in the first place one usually does not have full information about the population. The sample may or may not be truly representative and it is necessary to judge the sample by certain criteria.

The size of the sample is important. A small one is usually not satisfactory and the larger the sample, the better it is likely to be. This is particularly true of random or choice samples and is less true of samples that are selected according to sound statistical principles. If prejudicial factors are operating, an increase in the size of the sample does not improve it until the size of the sample approaches the size of the population, at which time the prejudicial factors are overcome.

The sample must be analyzed carefully to judge whether or not the factors of selection have been statistically sound. Let us take an example pertaining to the selection of foster children. Studies have been made purporting to show that foster children in better homes improve more in intelligence than do foster children raised in less favorable homes. The data lead to this conclusion if we can be sure that the foster children placed in homes of different grades or qualities were comparable at the time of placement. This situation probably does not exist because the foster parents having better homes are probably more intelligent and discriminating and probably select foster children of greater potential capacity. They look into the background of the children and select those who are more promising, while less thoughtful foster parents are not apt to select in so careful a manner.

Sometimes the principle of the normal curve is invoked to test a sample. It is assumed that if the sample is normal it is a good accurate one. This is probably true if the population is normally distributed, but it is possible and even probable that the population is not distributed normally. In such a case the sample should not be distributed normally but be distributed similarly to the population.

A good check is to take additional samples and compare them. If the various sam-

SARMIENTO, DOMINGO FAUSTINO

ples are similar, it is safe to conclude that any sample is a good one. H.S.

SARMIENTO, DOMINGO FAUSTINO (1811-1888). Domingo Faustino Sarmiento was the greatest of Spanish-American educators. He was not a specialist in the field of education nor in any other single area; his was the complete, the all-embracing mind, and he represented better than any one else the heroic creator of a nation, Argentina, his native land, in the formative period of Spanish-American nationalities. Born in the first year of Argentina's independence, he lived more intensely than any other Argentinian the chaotic, dramatic, heroic process of his nation's history, the civil wars, dictatorships and the attempts to organize the country along modern lines which marked the first fifty years of Argentina's existence. He was president of the Republic from 1868-74, and before he died, in 1888, he was privileged to see his nation definitely constituted along the lines of the ideas he had expressed in his writings fifty years before and which he had upheld with a determination, tenacity, and strength of conviction which place him among the Titans of history. A rugged individualist, an outstanding example of this as of all the other characteristic traits of his Hispanic race, he always fought alone, and often against everyone else. His strength came from no social or collective party or group, but from his own personality.

Among the ideas with which he identified his turbulent, passionate personality was that education is the principal factor in the formation of a nation. "We must make a school of the whole Republic," was the dogma he upheld, not only theoretically in his books, *Educación Popular* (1849), and *La Educación Común* (1855), but in practice as well, in every possible way, as teacher, statesman, journalist, and propagandist. His passion for education displayed itself in so many aspects and activities that it would be impossible to summarize and enumerate them. His vocation as a teacher began when, at the age of fifteen, he founded the first of the hundreds of schools he was to create in the course of his full life. In 1839 he founded in his native city, San Juan de la Rioja, the first school

for girls in Argentina, and made the first of the countless speeches he was to deliver throughout his life on the occasion of the opening of a new school or of some other type of educational center all over the Republic. During his exile in Chile (1840-45) he was actively engaged in educational work as Director of the first Normal School of South America. He wrote school texts, among them a graduated method for learning to read, *Metodo de lectura gradual*, which was published the same year as his literary masterpiece, *Facundo*, the outstanding work of Spanish-American literature, which has been translated into four languages. (The English version was by Mrs. Horace Mann.)

From 1845-48 he was commissioned by the Chilean government to travel in Europe and the United States to study primary education there, and on his return he published his books, *Viajes* and *Educación Popular*. Of the latter work Barnard said: "No such work had ever appeared in the Spanish language, and its merits are surpassed in no language."

His ideas on education came from European sources, principally French. But from his early youth, when he learned English by reading Franklin's autobiography, he had been a fervent admirer of the United States, which was to him the model of the democratic education he planned to introduce in his country. After this first visit he returned to the United States as Argentine Minister in Washington (1865-68). He knew, admired and followed Horace Mann; he was the friend of the American educators, writers, and scientists of his day; and he brought American methods and teachers to Argentina. His intimate contact with Mann, Barnard, and other leaders of the Common School Movement in the United States confirmed his faith in the efficacy of popular education as a *sine qua non* of republican government. All in all it may be said that he has been one of the outstanding promoters of inter-American relations.

Before his second trip to the United States he was Superintendent of Schools in Buenos Aires (1856-62), a post he gladly resumed after leaving the presidency of his country, and which he held from 1875-79 and in 1881. On his election to the presidency of Argentina he made a memorable address to the teachers of Buenos Aires, in which he emphasized the preeminent rôle education had held in his political activities all his life.

His earlier work in Chile (to 1855) and his later work as Minister of Public Instruction in Argentina and later as President of the Republic (1868-74) was grounded upon two principles which he considered basic for the development of an efficient system of popular education. One of these was that education must have national direction, manifesting itself through liberal appropriations in aid of schools in the provinces. The other was the need for normal schools. But, with Sarmiento, there was a postulate deeper than either of these; namely, that a republican form of government was impossible unless it rested upon a system of popular education.

On the fiftieth anniversary of his death in 1938 a tablet was placed upon his grave with the following inscription: "The Argentine nation to the memory of the President of the country and the school-master, Domingo Faustino Sarmiento." His merit as an educator lay less in the originality of his ideas than in his genius for converting these ideas into vital forces for the building of a nation. SCHEDULE, DAILY. The daily schedule is the chart or plan of the organized, day-by-day activities of a school. It shows the arrangement of class groups and the so-called extracurricular activities of the school. The daily schedule is known by a number of other terms: schedule of recitations, school program, general schedule, schedule of classes, daily class schedule, and the like. The practice in current literature is to use the expression *daily schedule* as the most comprehensive and descriptive one.

The daily schedule of the elementary school teacher is relatively simple since the pupils are usually in one room and generally under the direction of one teacher. Such a schedule

gives (1) the time of opening and closing of the morning and afternoon sessions, (2) the time and length of any intermissions in either sessions, and (3) the time and length of the various class, activity, and study periods. (See PROGRAM, DAILY.)

The daily schedule of the high school, however, is more complex and more difficult to prepare since a number of classes or activities of the high school are conducted simultaneously. The high-school schedule generally indicates (1) the time of opening and closing of the school day, (2) the time and length of any intermissions, and (3) the time, place, and instructor in charge of each recitation, laboratory, activity, or study period.

Studies concerning schedule-making show that the preparation of the daily schedule of the high school is usually a task of the school principal or assistant principal. Its preparation is one of the school administrator's major responsibilities, for the successful functioning of the high school is largely dependent upon the careful preparation of the daily schedule. In building a daily schedule there are involved several factors and features, some of which are relatively fixed. Some of the items to be considered in schedule-making are (1) expected pupil enrollment; (2) number of available teachers and their teaching fields; (3) number, size, and suitability of rooms; (4) curriculum; (5) requirements of the state department of education, regional accrediting association, and local board of education; (6) customs and traditions of the local community; (7) length of school day; (8) number and length of periods and intermissions between periods; (9) pupil-teacher ratio; and (10) plan of daily operation—continuous or double-session.

In addition to considering the above items the schedule maker should give some thought to general college entrance requirements, plans for grouping or sectioning pupils, and distribution of subjects between the morning and afternoon so that no pupil will be particularly overburdened with classes in either half of the day. The principal of the small high school will need to explore the possibilities of combining certain class groups and alternating certain subjects by semesters or years in order to avoid very small classes. For example, juniors and seniors may be combined one year for English Literature and the

SCHEDULE, DAILY

following year for American Literature. This is an example of both combination and yearly alternation.

To facilitate schedule-making, it is recommended that high-school principals, especially beginners, secure copies of former daily schedules of their schools and as much information as possible concerning the items already enumerated herein.

There are two general practices in schedule making, which are diametrically opposed to each other: (1) having pupils register from a more or less arbitrarily prearranged schedule, which is often the same in a given school, year after year, and (2) conducting a preliminary registration, or choice of subjects, and then making the schedule in terms of the pupils' choices. While the first method is more convenient administratively, it is generally considered undemocratic and poor administrative policy. The second method is the one recommended and followed by the better school administrators.

The preliminary registration should be made several weeks before the end of the first semester or the end of the school year. It is especially during this preliminary registration that the school should practice effective pupil guidance. Many school administrators require that the pupils' choice-of-subject blanks be signed by the parents.

Largely upon the basis of this preliminary registration and with other related facts in mind, the administrator sets himself to the task of preparing the daily schedule. There are at least two helpful mechanical aids that he can utilize. One of these is the *schedule board*, the form and size of which vary according to the needs and preferences of each school. The names of the various teachers, arranged alphabetically as a group or by departments, are placed along one margin. The daily periods are placed in sequence along the other margin. Spaces or pockets are provided for the various proposed class and activity sections. For these spaces or pockets there are prepared small movable cards or blocks having on them the names or sections of the different classes or activities. These can be shifted about on the schedule board to produce the best organization.

The second mechanical aid is the *conflict sheet*, which has the various subjects or activities listed in the same order on both

margins. The sheet is ruled horizontally and vertically. At the proper intersections tallies are made from the pupils' choices in their preliminary registration. This procedure is time-consuming, but can be done by the clerical staff. The purpose of the sheet is to show at a glance what subjects will conflict with one another and the number of conflicts between any two subjects. Thus the schedule maker, in his use of the schedule board, can determine from the conflict sheet what subjects it is unwise to plot in the same period of the day. This procedure will not remove all conflicts, but the number can be lessened.

The three most general plans of building the daily schedule are the *block*, *mosaic*, and *combination methods*. The block method may be used where there are a sufficient number of pupils taking the same combination of subjects to provide for one or more sections of the various subjects. Such subjects may be omitted from the conflict-sheet tabulations and immediately inserted in the master schedule. The mosaic method involves the shifting of the cards or blocks on the master schedule to avoid the conflicts evident in the conflict sheet, and must be used for those pupils whose registrations make it impossible to use the block method. The combination method is the one generally used and, as its name implies, is a combination of the block and mosaic methods. In all these methods a certain amount of trial-and-error must be employed, although practice in schedule-making will tend to reduce it. The high-school principal will soon learn by experience certain short cuts in his work.

A few large schools make use of business machines such as the *Hollerith* for sorting and counting cards punched with the data from the pupils' preliminary registrations. The price of this equipment, however, is prohibitive for most schools. (See PROGRAM, DAILY.)

SCHOLARSHIPS AND FELLOWSHIPS, INTERNATIONAL. In the field of international scholarships and fellowships during the last forty years, the United States has probably led the world in the number of foundations and the number of students concerned. The pioneer in this field, however, the man who established the first and the best known plan, was not an American but an Englishman who lived his life in South Africa, Cecil John Rhodes. When Rhodes died in 1902 and his famous will was published there were, aside from the Boxer Indemnity Scholarships, only a few scattered opportunities for international study. The Rhodes will was one of the most daringly imaginative documents in the history of education. By it were established approximately two hundred scholarships for students from the United States, the British Dominions, and Germany, for study at the University of Oxford. Nearly one half of these appointments went to the United States—two for each of the forty-eight states, or ninety-six in all.

During the period of nearly forty years since the first Rhodes Scholars were selected in 1904, more than two thousand men from the various countries concerned have pursued their studies at Oxford. There are more than one thousand ex-Rhodes Scholars living in the United States; they may be found in every corner of the country and in almost every occupation.

The success and the prestige of the Rhodes Scholarships have been such as to exert an important influence on American philanthropy, in the first place by bringing about the establishment of systems of fellowships reciprocating the Rhodes Scholarships, bringing English students to study in American universities; and in the second place by influencing the establishment of funds with a similar purpose, offering American students other opportunities for study abroad.

Since the Rhodes Scholarships were established opportunities have been created in the United States for bringing each year as many Englishmen—indeed more—to study in

American universities as there are American Rhodes Scholars going to Oxford. The Commonwealth Fellowships bring the largest number and most definitely reciprocate the Rhodes scheme. There are, in addition, the Davison Fellowships to Harvard, Yale, and Princeton; the Choate Fellowship to the Harvard Law School; the Procter Fellowships at Princeton; the Riggs Fellowships at the University of Michigan; and the Henry Fellowships to Harvard and Yale.

The second general result of the Rhodes Scholarships is the establishment of American foundations with a similar purpose. The most important of these is the John Simon Guggenheim Memorial Foundation, offering research opportunities to older scholars, suggested to the founder in the first instance by the example of Rhodes and organized and administered by Rhodes Scholars.

The Guggenheim Foundation is intended for scholars who have already demonstrated unusual aptitude for independent research or for creative work in any one of the Fine Arts, including music. American fellows may study in any country where their work may best be done and they work under the freest possible conditions. In addition to appointments for American scholars to work in this country or abroad, the Guggenheim Foundation offers fellowships in a steadily increasing number of countries of the western hemisphere for scholars who wish to pursue their researches in the United States. These countries include at present Canada, Mexico, Cuba, Puerto Rico, Brazil, Uruguay, Argentina, Chile, and Peru.

Other systems of international fellowships open to American students, all owing something to the Rhodes example, are the Henry Fellowships to Oxford and Cambridge; the fellowships established by the Commission for the Relief of Belgium, for study in Belgian universities; the American Field Service Fellowships to French universities; and the fellowships offered by the American Academy in Rome, the Institute of Current World Affairs, the Kosciuszko Foundation, the Lalor Foundation, and the Oberlaender Trust.

Even more widely extended are the appointments, varying in number and plan from time to time, offered by the Rockefeller Foundation, which bring scholars from other countries to the United States, from the United

SCHOLASTIC ABILITY

States to various European countries, and from one European or South American country to another. The Carnegie Corporation has likewise, without establishing any single uniform scheme, supported a large number of individuals whose plans made it necessary for them to go from one country to another for study and research.

The Institute of International Education, which administers the American Field Service Fellowships to France, supervises also a large number of appointments open to foreign students who wish to study in the United States or to American students who wish to study in some foreign country. Many of these fellowships are supported by small funds; others are individual exchanges. There are some twenty-five or thirty countries involved in these exchanges and the total number of students going in one direction or the other has in recent years varied between 6,000 and 9,000. (See also RHODES SCHOLARSHIPS.) F.A.

SCHOLASTIC ABILITY. Scholastic ability, as distinct from scholastic aptitude, indicates what can actually be achieved in school work, while the latter signifies what could be acquired with proper motivation and training. Theoretically, scholastic aptitude for all but the manual skills is supposed to be very closely correlated with intelligence. Actually, correlations between school achievement and I. Q. or mental age have not been found to be high. These correlations vary depending on the particular tests used, the particular subject-matter tested, and the particular groups tested. For example, correlations ranging from $+0.50$ to $+0.90$ have been found for different reading tests and intelligence. On the whole, the more verbal and abstract the subject-matter (e.g. reading and arithmetic reasoning), the higher the correlation with intelligence. The more concrete the task, the more it can be learned by rote, the more manual in nature (e.g. arithmetic computation and handwriting), the lower is the correlation with intelligence. One study found that among the same group of children the correlation between intelligence and the understanding of arithmetic was $+0.60$, while that of intelligence and arithmetic computation was $+0.35$, and that of intelligence and handwriting was only $+0.21$.

In spite of the fact that the correlations

found between school achievement and mental age are not very high, it has become customary to expect every child to "live up to his intelligence" in subject-matter achievement. This means that we expect him to reach a standard of achievement corresponding to the norm or average for his mental age. The concepts of *educational quotient* and *accomplishment ratio* have been introduced to describe whether the child does maintain such a level of achievement. (See EDUCATIONAL AGE.)

However, when correlations between intelligence and achievement in a particular subject are $+0.60$ and lower, accomplishment ratios will show a wide range both above and below 100. It is not fair, therefore, to expect all children to reach the mean school achievement for their mental age. Such an expectation signifies a belief that if all the children were properly motivated, they would all reach at least the level of achievement which is at present the average for their mental age. There is not enough justification for such an assumption. It is true that with better teaching the achievement norms for each age might be raised considerably, so considerably that the pupil who scores farthest below the norm at that time makes as high a score as the present average. However, if such an improvement were brought about, it would not necessarily mean that the range of achievement at any mental age level would decrease. The new norms would be higher but there might be the same number of E.Q.'s that did not correspond with the I.Q.'s. While better teaching should be expected to improve achievement, it would not follow that the correlation between intelligence and school achievement would be raised. However, it is important to bear in mind that even if one believes that the quality of a person's intelligence changes little throughout life, the fact that so many types of achievement have so low a correlation with intelligence means that there are other factors, many of them open to deliberate change, which also affect the standard of achievement.

Correlations between school achievement and intelligence are lower in high school than in the elementary school, and still lower in college. The decrease in the correlation with the level of schooling does not mean that intelligence counts for less at higher levels of

education. It is due partly to the fact that the range of intelligence is greatest in the elementary school and least at the college level. When the group upon whose measurements correlations are based has a narrow range in one characteristic, the correlation between that characteristic and another will be lower than if a group of wider range had been chosen (See CORRELATION). Another reason for the low correlation between measured intelligence and measured scholastic ability in college is the fact that in first class colleges only persons of high intelligence are admitted. A higher intelligence than the average for students at these colleges is not necessary for the attainment of high marks in most of the college subjects as taught and tested. What counts more in determining college success are motivation, study habits, general personality adjustment, and the amount of time available for study. Some colleges which admit most of their students on their high school records alone and the rest on the basis of entrance examinations find that those who have shown good high school ability also prove themselves abler at college than do those who did not do so well in high school but did do well on the entrance examinations, a finding which tends to corroborate the importance of motivation and study habits for college achievement.

At all school levels intelligence is more highly correlated with general achievement than it is with achievement in specific subjects. Special *prognostic tests* for specific subjects such as foreign language and mathematics and reading (called reading readiness tests) are being introduced to predict to what degree a pupil will be successful in undertaking specific training in that subject at that time. Prognosis tests used together with intelligence tests are better than either used alone. Both, however, predict much better those who will not succeed than they differentiate between those who will gain a high degree of success and those who will realize average achievement. It is customary to find the *critical score* on each prognosis test. Students scoring below the critical score have so little chance of succeeding in the subject-matter for which the test is prognostic that they are usually not permitted to proceed with that study at that time. (See PREDICTION OF SUCCESS and PROGNOSTIC TEST.)

It is often assumed that scholastic ability

can be predicted from scholastic interest. Many years ago Thorndike found a correlation as high as $+0.89$ between educational interests and self-estimated abilities. This correlation proved to be much too high when the problem was further investigated and when other measurements of abilities than self-estimations were used. Investigations which compared self-estimated interests in college courses both with self-estimated abilities and with college grades found that the correlation between interests and grades was much lower than that between interests and self-estimated abilities. In many groups the average achievement of students preferring a subject was no higher than the average achievement of the rest of the class. However, a much larger percentage of students who prefer a subject make their "best grades" in that subject and a smaller percentage made "worst grades" than do students as a whole.

Numerous studies have been made of the correlation of abilities in the various school subjects. Success in one subject, such as mathematics, has been correlated with success in other subjects, such as science, social science, English, etc. Some investigators have studied the correlation between success in one phase of a subject with success in another phase of the same subject; for example, the correlation between ability in arithmetical computation and in problem solving, and between knowledge of grammar and composition ability. As is to be expected of investigations which deal with so many different situations, there has been a wide range in the coefficients of correlation reported, with most coefficients of correlation between ability in one subject and ability in another subject falling within the limits $r=+.30$ and $r=+.60$. The closer the similarity in content and procedure, the higher is the coefficient of correlation between success in one subject and success in the other. Thus, the correlation is higher between elementary algebra and intermediate algebra than between elementary algebra and physics; the correlation between elementary algebra and physics is higher than the correlation between elementary algebra and English; and the correlation between elementary algebra and English is higher than between elementary algebra and health education. Significantly enough, wherever large and relatively heterogeneous groups of pupils are studied, the cor-

relations found are positive, though they may be low. There is no school subject in which success is regularly, or even often, correlated negatively with success in another subject. Since coefficients of correlation reflect the scores of groups of students, the prevailing positive correlation of ability in school subjects does not mean that individual students may not be successful in one subject and fail in another. SCHOOL YEAR, LENGTH OF. The *school year* may be defined as the length of time the school is in session. There are several factors which determine the length of time any given school may operate within the calendar year. Among those factors are the following: (1) the wealth of the state or community, and (2) the amount of the tax money the citizens are willing to set aside for educational purposes.

Many people are not aware of the wide differences in the scope and quality of public school programs in the several states. Length of school year is only one of the factors which undoubtedly reflect those differences to a significant degree.

In 1939-40 the average school term in the nation as a whole was about 175 days, or $8\frac{3}{4}$

months. In the individual states the average term ranged from 146 days in Mississippi to 188 days in Maryland. While thirteen states operated their schools for at least nine months, on the average, four states kept theirs open for less than eight months and eleven operated for less than $8\frac{1}{2}$ months.

In each state, of course, approximately one half of the school children had terms that were shorter than the state average and, in general, rural school terms were much shorter than those in urban areas. In the rural schools of Mississippi the typical term in 1937-38 was only 136 days while in the urban schools of the same state it was 177 days. For the whole nation the average length of rural school terms was 166 days, as compared with an average term of 181 days in urban schools.

Most of the states ranking lowest in length of school term are in the Southeast while those ranking highest are located chiefly in the Middle Atlantic, New England, and Middle states. O.G.J.

SCIENCE, TEACHING OF. Throughout the elementary and junior high school, the subject matter of science instruction is undifferentiated and is known as *science* or *general science*, the first term tending to supersede the second, especially in the elementary grades. The subject matter of any unit of instruction in these schools is not restricted to the fields of the specialized sciences, such as botany, zoology, astronomy, physics, chemistry, geology, or meteorology, although it includes information and principles formally belonging to each of these fields.

In some high schools General Science is offered in the tenth, eleventh, and twelfth grades. The science course most frequently offered in the tenth grade is biology, a course which varies greatly in content from school to school. Earlier textbooks had a tripartite organization of units of botany, zoology, and human physiology. Stress during the twentieth century has been placed successively on such central ideas as evolution; the relation of organisms to man as actual or potential wealth (economic biology); organisms as users of and competitors for energy; physiological processes, emphasizing human physio-

logy; social and civic problems, such as individual and community health, genetics, mental hygiene, conservation, and consumer problems.

Chemistry and physics are the dominant science subjects in the last two years of the high school. Although the trend in these fields is away from the systematic or disciplinary content characteristic of earlier periods and toward practical problems of everyday life, much less change has taken place here than in biology.

Small and ever decreasing enrollments throughout the country still persist in various other science courses, the most frequently elected among which are botany, zoology, physiology, geology, and astronomy.

On the college and university level science courses are more highly diversified, specialized, and departmentalized than on lower levels. A few institutions offer orientation or survey courses which cover areas wider than those of the usual "department," but such courses have not met with general favor. Courses in general biology are fairly numerous, but frequently, especially in the larger institutions, the study of living things is undertaken in courses devoted to such smaller areas as botany, zoology, bacteriology, entomology, etc. General courses in chemistry and physics are offered for college freshmen and sophomores after which chemistry is commonly departmentalized into inorganic, organic, physiological, and physical chemistry, while the process of subdivision in physics culminates in the specialties of mechanical and electrical engineering. Technical schools of engineering, agriculture, horticulture, home economics, mining, etc., adapt their science courses to the particular needs of their respective fields.

Aims of Science Teaching. Statements of aims of science teaching are abundant in the literature of the field. They may be subsumed under the following heads: (1) Attitudes, ideals, and appreciations, (2) Methods of thinking, (3) Concepts or generalizations, (4) Useful information, (5) Experience, (6) Mental discipline, (7) Preservation of the racial heritage, (8) Preparation for further study.

By *attitudes, ideals, and appreciations* are meant certain desirable mind-sets, such as confidence in the universality of cause-and-

effect relationships, curiosity, and respect for the points of view of others, as well as the ability to enter into a wide variety of emotional experiences, such as awe in the presence of the marvels of nature, joy in discovering new truth, admiration for the efforts and achievements of scientists.

No sharp distinction can be made between mind-sets and emotions on the one hand and methods of thinking on the other. Both are involved in what is commonly called "scientific method." The method of thinking which science teachers attempt to make functional in their students consists essentially of a series of steps among which are (1) the clear recognition of a problem or uncertainty the resolution of which is sought, (2) the analysis of such a problem into its essential elements, (3) the gathering of pertinent facts or data, (4) the formation of appropriate hypotheses and the clear distinction between a hypothesis so formed and a conclusion, (5) the testing of hypotheses by means of facts already available or obtained for this purpose, and (6) the rejection or acceptance of the hypothesis in the light of data. If a hypothesis is rejected, a new one must be made and tested; if accepted, it becomes a conclusion, a new piece of knowledge to be utilized.

Prominent in writings on the objectives of teaching of science is the large generalization or concept, an idea or understanding which serves to unify and explain large areas of human experience. Illustrative of such generalizations are the following: "The sun is the chief source of energy for the earth" and "All life has evolved from simple forms".

Useful information as an objective of science teaching is self explanatory. Sense experience necessary in the attainment of other objectives or valuable for its own sake and not common in out-of-school experience must be supplied by the school. Mental discipline, in spite of the weight of evidence against it, is still regarded by many teachers as the central purpose of their teaching. The preservation and transmission of scientific knowledge from generation to generation is a defensible purpose for teaching science on advanced levels. Preparation for further study finds decreasing recognition in the elementary and secondary levels, but is a clear purpose on professional and pre-professional levels.

SCIENCE, TEACHING OF

In recent years various attempts have been made to state the objectives of science teaching in terms of resulting pupil behaviors. Outstanding among such efforts is the report of a committee of the Progressive Education Association, entitled, *Science in General Education* and the 1942 report of the National Committee on Science Teaching.

Procedures. On the college level, the prevailing methods of science teaching are lecture, lecture-demonstration, individual laboratory work, recitation or quiz, and examination, while advanced graduate work generally consists of research projects in which the definition of the problem and the methods of procedure are the student's responsibility.

In the middle and lower schools, a greater variety of methods is used. Here the tendency is markedly away from lectures, specific text assignments, and formally prescribed laboratory exercises.

In attempting to adapt the work to the varying abilities, interests, and learning rates of pupils, teachers frequently have recourse to workbooks or worksheets which are sets of more or less specific directions, including laboratory exercises; study guides; questions calling for written answers or for charts, lists, drawings, etc.; suggestions for special reports; and reading lists, etc., on which each pupil works at his own rate and with considerable latitude in the tasks he undertakes. This general method is found as a part of certain recognized procedures among which are the Morrison Unit (*q.v.*), the Contract or Dalton Plan (*q.v.*), although variations may occur in almost any procedure.

In the lower grades and less frequently in the high schools, projects are undertaken by the class as a whole or by small groups within the class, in the execution of which the aims of the course may be realized. Ideally such projects originate with the pupils and have social values which they recognize. This method lends itself readily to the establishment of desirable attitudes but less well to the development of systematized understanding and knowledge. In the hands of a skilful teacher it yields excellent results by affording natural motivation and integration of science with other school work and with life outside of the school.

Laboratory work based on specific direc-

tions and called "experiments" has declined in recent years. (See *LABORATORY METHOD*.) The present tendency is to use lecture demonstration (*q.v.*) for the purpose of interpreting scientific facts, generalizations, and principles and to use the laboratory for the solution of problems which are real to the pupils. Many studies have been made experimentally of the relative merits of individual laboratory work and demonstration. Though contradictory and inconclusive in their findings, these studies have afforded some justification for reducing the amount of individual laboratory work.

The use of such audio-visual aids in science teaching as the school journey; collections of objects, models, and specimens; and flat and projected pictures, especially moving pictures, is increasing rapidly. Excellent slides and films are now available at a reasonable cost. There is sound experimental evidence that learning is substantially increased by the use of such aids. (See *AUDIO-VISUAL AIDS*; *MUSEUM, SCHOOL*; *TRIP, SCHOOL*.)

Science teachers through their organizations and publications are attempting (1) to relate their instruction more closely to the life needs, interests, and behaviors of their students, and (2) to develop and gain acceptance of a 12-year program covering the elementary and secondary school periods, which shall be sequential and integrated.

Tests. During the decade covering approximately the years from 1924 to 1934 more than two score printed tests were published for use in high school science classes. The majority of these tests are directed to the measurement of achievement, chiefly in terms of knowledge, and are highly objective. Included among the printed tests are aptitude, diagnostic, and instructional tests; some are devoted wholly or partly to attempts to measure certain less definite outcomes such as attitudes, scientific thinking, and laboratory resourcefulness. In recent years the Co-operative Test Service has developed several series of excellent tests. (See *STANDARDIZED TESTS*.)

SCIENTIFIC STUDY OF EDUCATION. Early in the twentieth century, the spirit of scientific inquiry and the practice of scientific experimentation began to influence the professional thinking of educators, resulting in a significant contribution to educational progress, that of scientific educational research. The earlier empirical and speculative thinking about education gave way to inquiries made in a rigid scientific spirit and pursued by the accurate and precise methods of modern science. Educators demanded that educational reforms be based on the findings of scientific research, and became increasingly skeptical of proposals not based on reliable statistical and experimental investigations.

This movement to study education scientifically has been designated as scientific determinism. The scientific determinist insists that all educational problems be approached in a scientific attitude; that all educational practices and procedures be determined by investigations conducted in the scientific spirit and by means of scientific techniques. The scientific method is (1) objective, (2) impartial, (3) mathematically precise, and (4) subject to verification by any competent observer. This is the method that the educational research workers use in determining such matters as educational aims, educational content, educational agencies, educational organization, and educational methods. They not only draw upon the basic sciences for their data, both in the form of facts and in the form of general principles, but they also

use the laboratory and statistical investigation procedures of the exact sciences.

Educational investigation and experimentation have developed rapidly in recent years. Scientific curriculum construction and scientific determination of teaching techniques have become accepted aspects of school administration. The work of the research specialist has rapidly expanded from that of making a general survey of accomplishment and of conducting testing programs to including a wide diversity of scientific studies dealing with such problems as pupil guidance and placement, pupil classification, retardation and elimination, curriculum reorganization, salary schedules and school finance, school architecture and school plants, school legislation, and even school publicity and public relations.

The scientific research workers have contributed much to the solution of school problems and to making education more efficient, but certain dangers should be avoided in this scientific study of education. In the first place, the research worker should remember that the measurement movement is in its infancy, and that we cannot expect to perfect in a few decades our measuring instruments in this realm of intellect, emotions, and social relations. In the second place, he must not reach the conclusion that only those things which can be measured objectively and concretely have value, and that we can safely throw overboard the work of the educational philosopher. In the third place, however scientific the research worker becomes, he must never depersonalize and mechanize the work of the schools, and allow children to become mere tallies in frequency distributions or mere numbers in case-studies. Finally, scientific measurements and statistical studies must never be allowed to become ends in themselves, but always should be used as means toward the more effective education of the children of our schools. Statistical manipulations should never be allowed to run away with common sense. (See RESEARCH, EDUCATIONAL.) E.H.W.

SCORE CARD — SCORES, CONVERSION OF

SCORE CARD—See BUILDING, SCHOOL; TEACHERS, RATING OF.

SCORES, CONVERSION OF. The *raw score* (*crude score*) is the numerical result obtained directly from the scoring of a test. A youngster to whom a standardized intelligence test has been administered may receive a score of 41 points, a number which represents only the total of the scores on each of the parts of the test. Raw scores have little absolute significance and cannot be compared from test to test since the size and the equality of the units used are unknown. It is difficult, for example, to interpret in any meaningful way the score of 41 points on an intelligence test. Raw scores can be made meaningful by comparing them with similar data previously acquired or by conversion of these raw scores to some form of derived scores. By using converted scores, that is, derived scores, rather than the original raw scores we are able not only to compare the child's ability or achievement with that of other children but also to compare his status in one trait or ability with his own status in another trait or ability. The conversion of scores also makes it possible to obtain a composite or over-all measure which represents in a single score a pupil's achievement in several subject areas.

Which type of derived score should be used in a given situation depends on the kind of interpretation that is needed. Scores on intelligence tests are usually converted into mental ages if a measure of mental level is desired or into intelligence quotients if the rate of mental growth is needed. Raw scores can be transmuted into age or grade units—they are then called age equivalents or grade equivalents, respectively—to enable comparison of the pupil's score in terms of the scores that children of various ages or grades receive on that test. (See NORMS.) When all that is wanted is a measure of the student's relative standing in his group or in a representative group of students who have taken the test, it is appropriate to convert the raw score into percentiles (*q.v.*), standard scores, or some similar measure in which scores are expressed in terms of their variation in standard deviation units from the arithmetic mean or some other agreed upon point in the distribution.

The *standard score* or *standard measure*,

often referred to statistically as a *z-score*, indicates the number of standard deviations by which, and the direction in which, the corresponding raw score deviates from the arithmetic mean of the distribution of raw scores. The formula for deriving this measure is

$$z = \frac{X - A.M.}{S.D.},$$

where X refers to a particular raw score in a distribution of raw scores and A.M. and S.D. refer respectively to the arithmetic mean and standard deviation of the distribution. Thus a standard score or z-score of 2.0 is two standard deviations above the arithmetic mean of the distribution, while a standard score or z-score of -1.5 is one and one-half standard deviation below the arithmetic mean of the distribution. In order to avoid using negative numbers, standard scores are sometimes computed from a zero point, usually fixed as being at the point three standard deviations below the mean. When this is done, the standard scores are all positive and express the number of standard deviation units that the given raw score is above the zero point. (A score at the mean of the distribution, for example, would be converted into a standard score of 3.0.) Although standard scores are not necessarily restricted to distributions which are essentially normal, they are more easily interpreted and more meaningful when so applied than when they are applied to skewed distributions.

When raw scores are converted into standard scores, an arbitrary score is in effect substituted for the original scale. Standard-score scales have several values not characteristic of raw-score scales. When the distribution is essentially normal, they afford a definite concept of the placement of each score in the series, they have various significant uses in statistical methodology, and they make possible the combining of scores from several tests into a reliable composite score. Percentile scores, which are counting but not arithmetical scores, cannot be averaged to obtain a reliable composite score; standard scores, however, can be averaged to produce a reliable composite measure.

Various other types of derived scores are based on the same principle as is the standard

score. Perhaps the best known of these is the T-score, for which the formula is

$$T = \frac{10(X - A.M.)}{S.D.} + 50,$$

where X, A.M., and S.D. have the same meanings as were attributed to those symbols above. Thus a T-score of 70 is two standard deviations above the arithmetic mean of the distribution, and a T-score of 35 is one and one-half standard deviations below the arithmetic mean of the distribution. The advantage of the T-score lies in the fact that, in large measure, the use of negative and decimal numbers is avoided.

Provision is made in many standardized tests for immediate conversion of raw scores into some form of derived scores based on the arithmetic mean and the standard deviation of the group of pupils on which the tests were standardized. Although the procedures used in obtaining the derived score scales for these tests differ in various minor ways, and numerical values do not necessarily have identical meanings for all, such derived measures as scaled scores, converted scores, and equated scores are similar in their usual method of derivation and in their meaning to standard scores and T-scores. For standardized tests of these types, the scaled scores, converted scores, or equated scores have more meaning than do their comparable raw scores, while percentile tables for various grade or age groups usually permit of still more exact interpretations for specific groups of pupils.

SCRAPBOOKS. A pupil scrapbook usually consists of a collection of pictures, maps, cartoons, graphs, etc. cut from magazines or other sources and mounted in some kind of bound or loose-leaf notebook, usually in an organized plan which parallels the work of some course. Though it has been used in all subjects and on all school levels from the primary grades through college, it is used most frequently in secondary school social science and English classes. The primary value claimed for the scrapbook as an edu-

cative device is that it encourages the student to look for illustrative material pertinent to the subject being studied. In a unit on the use of Greek mythology in modern writing, for example, advertisements using classical allusions can be cut from magazines and newspapers and placed under appropriate headings in a scrapbook. When used as a functional part of a planned unit, it can be very helpful in enriching and motivating the subject under study, especially if the students share their material with the others in the group. However, the scrapbook can represent a serious waste of energy if it is merely a haphazard conglomeration of unorganized material having little pertinence to the subject being studied, or, if a premium is put on elaborate make-up at the expense of a planned, helpful content. In an increasing number of classes, the teacher is encouraging the students to keep scrapbooks as a cooperatively planned undertaking, rather than requiring each student to prepare one for himself.

T.M.R.

SEATING, CLASS. The seating arrangement in the classroom will depend on the activities to be carried on and the needs of the students in relation to these activities. If, for example, the work of the day is to revolve about the teacher's expositions, then the students with hearing and vision problems should be seated closest to the teacher. On the other hand, an informal group discussion in which the students take a major part requires that those weak in hearing and vision be seated as close to the center of the group as possible. Any inflexible arrangement that is to hold for all times and all activities is inadvisable.

The possibility of flexible seating arrangement is often limited by the immovability of fixed seats and desks. The informal circle arrangement, for instance, which is often favored for group discussions, is impossible under conditions in which seats are immovably directed toward only one side of the room. All learning needs can be satisfied only when easy readjustment and rearrangement of seating equipment are possible. (See **SCHOOL FURNITURE.**)

SECONDARY EDUCATION

C. M. REINOEHL and F. C. AYER, *Classroom Administration and Pupil Adjustment* (D. Appleton-Century Co., New York, 1940).

SECONDARY EDUCATION. Secondary education in this country is usually regarded as society's organized effort to educate its adolescents. It comprises the junior high school (*q.v.*) and senior high school and in some cases the junior college (*q.v.*). Thus ages 12 to 18 (sometimes 12 to 20) are usually included. Chronological or physiological age therefore is as a rule the limiting factor in defining the scope of secondary education.

Aims. H. C. Morrison attached another definition during the third decade of this century. He thought of secondary education in terms of intellectual rather than physiological and social growth. The secondary education period begins, Morrison assumed, when an individual has acquired the primary adaptation necessary to develop the "art of study." Those adaptations—reading, number and primary social—could be expected by the beginning of the fourth grade. The pupil's intellectual behavior after this period, it was contended, differed from that of the older student in degree rather than in kind, whereas his behavior before this period differed in kind. In thus defining secondary education Morrison unwittingly reverted to the European pattern and disregarded the tendency in the United States of emphasizing the social characteristics of the individual. The Morrison definition was not widely accepted in practice, even though certain phases of the mastery technique associated with it stimulated general interest for a time.

The fact that society generally has refused to confine the meaning of secondary education to intellectual growth is highly important. When it insisted that the schools must give due regard as well to the physical, social, and emotional development of the individual, it defined secondary education in such a manner as to condition its further organization, curriculum, method and relations with the nonschool world. In other words it oriented the secondary school away from the European pattern, which we had been wont to accept as ideal.

Today secondary education has gradually accepted, at least in theory, the principles

that the purposes of secondary education are to:

- (1) enable all individuals to grow from childhood to adulthood,

- (2) enable each adolescent to develop his potentialities to their maximum degree,

- (3) insure that each adolescent makes a vocational choice that satisfies his interests and challenges his capabilities,

- (4) insure that he secures such orientation to his vocational choice as will enable him to make an effective adjustment to it,

- (5) provide such orientation to his community and the world at large as will permit him to take an intelligently active part in the solution of civic problems,

- (6) provide such orientation to family life as will enable him later to assume an intelligent role as a parent, and

- (7) accomplish the above purposes with a full realization that only as adequate consideration is given to the physical, social, emotional, and mental nature of the individual will the resulting growth enable him to function with optimum effectiveness.

That the above aims have not been generally accepted in practice and are even not clearly in the minds of all as suitable objectives is indicated by the fact that during the fourth decade of this century the Department of Secondary School Principals of the National Education Association outlined the issues in, and the function of, secondary education. Among the issues were included such questions as:

- (a) Shall secondary education be provided at public expense for all normal adolescents or for only a limited number?

- (b) Shall secondary education provide vocational training or only general education?

- (c) Shall secondary education present merely organized knowledge, or assume responsibility also for attitudes and ideals?

A glance at the development of secondary education in this country will reveal the reason for the lag between practice and theory.

Development. Initially, secondary education was primarily college preparatory and for only a highly selected group. It was selected, however, not by design but because the fashion of thinking that the secondary school was the "people's" school had not as yet been generally accepted.

By the middle of the 19th century the

demands of a pioneering people had forced certain practical subjects into the curriculum in competition with the academic courses. These had their origin in the academy movement, which spread through this country during the first half of the 19th century, and which was the first expression on a large scale of the will of the people for a form of secondary education that fitted our democratic ideals.

Educators interested in college preparation were alarmed during the last years of the 19th century by the many short courses of questionable disciplinary values. An academic curriculum comprising English, Latin, mathematics, history, a modern language, and science was recommended as the acceptable program for all secondary schools. By this means the emphasis again was shifted from secondary education as a people's movement to secondary education as a college preparatory concept.

During the second decade of the 20th century the junior high school came into existence and the Committee on the Reorganization of Secondary Education made its Seven Cardinal Principles report. In addition, the secondary school found a rapidly increasing population in its midst. This tendency toward democratization suggested the need for a program more closely articulated with the needs of the less highly selected group of boys and girls.

Various industrial and business groups in need of more trained workers knocked at the doors of secondary education, and vocational courses were introduced in constantly increasing numbers. The federal sponsored and supported Smith-Hughes provision for vocational education gave impetus to vocational education. More recently the George-Deen Act, also providing financial assistance from the federal treasury, encouraged the introduction and expansion of distributive education. Furthermore, adult pressure groups concerned about health, thrift, citizenship and other social-civic values also wanted their peculiar interests represented.

These many demands on the part of the public, expressed either through local pressure groups or through state and federal legislation, have created a type of secondary school very different from that of the early part of the century.

Legal status. Students of secondary education must realize, however, that the status of the secondary school as part of society's effort to perpetuate the democratic tradition is not fully settled in the minds of all influential citizens. It is therefore likely to be a recurring issue, particularly when avenues of national economy are sought.

In 1876 the Supreme Court of the country was asked to rule on the legality of taxing people for the support of secondary education. It was contended by the opposition that it was the purpose of the pioneers in the country to provide education of only elementary grade for the masses. The decree, in what is known as the *Kalamazoo case (q.v.)*, favored the right of society to tax itself for public education beyond the elementary school level. This decision, the tendency of youth to seek increased educational opportunities at public expense and the practice of society during period of economic stress to pass legislation that postpones the age at which youth may leave school, thus removing young people from the competitive job markets—these insure that secondary education at public expense for all youth has come to stay in this country.

But how much education, for how long, and of what kind, are questions which closely affect the cost of secondary education and are therefore likely to be debated recurrently for some time to come.

Organization. For example, shall public education be provided only until the end of the 12th grade (or in some states the 11th grade), or shall it be extended through the junior college years? or even into the four-year college and university for those who can profit from it? Shall a community establish a vocational school to give training in skills needed in industry, agriculture, business?

In 1910 there were 4,249,000 youths in the country between the ages of 14 and 17. Of this number 915,000 attended public secondary schools and 117,410 the private secondary schools—a total of 1,032,410, or 25 per cent of the youth at that time. The percentage had increased to 65 per cent by 1930 and to 73 per cent by 1940.

The 1940 census showed 9,720,600 youths between the ages of 14 and 17. Of these, 6,601,400 were enrolled in public secondary schools and 457,700 in private secondary

SECONDARY EDUCATION

schools, a decrease of nearly 50 per cent in the proportion of youth in private schools.

These data reveal that not only has the proportion of 'teen age boys and girls who come under the influence of the secondary school increased rapidly in the last generation but the proportion who attend the public rather than the private secondary school is also increasing.

As a result of this increase in numbers, as well as of a growing emphasis on the needs of individuals, secondary education is changing its form of organization. Traditionally, it has been a four-year school superimposed upon an eight-year elementary school, and sometimes followed by a four-year private or parochial college. With the advent of the junior high school movement in the second decade of this century the original 8-4 form of organization was replaced by a 6-3-3 or 6-6 type of school.

The development of the junior college in certain sections of the country added two years to public secondary education. At first this created a 6-3-3-2 form of organization, but gradually a 6-4-4 plan is evolving. These plans of organization are designed primarily, however, for the program of general education leading to college admission. (See EDUCATIONAL LADDER.)

As society increasingly accepts public education as being concerned with vocational orientation, specialized training is brought to the fore. The vocational education may be two, three, or four years in length, depending upon the vocation for which preparation is sought. This preparation may be provided as an adjunct of general education in a comprehensive secondary school or in a school which specializes in vocational preparation. The vocational preparation may also be viewed primarily as training and retraining for special vocational activities, or as education, namely, as intelligent orientation to a general field of vocational activity.

No longer may we say therefore that the organization of secondary education must be of a 6-3-3, or 6-4-4, or any other type. Instead, its organization will become increasingly varied, depending upon the needs of the pupils and the demands of society for specialized education.

Another problem affecting organization arises from the size of the school unit. With

the emphasis on efficiency and consolidation and the resulting larger administrative unit, secondary schools of several thousand pupils are not uncommon in urban communities. It must be remembered, however, that the median-size secondary school in this country has less than 100 pupils. Increasingly, educators are becoming aware of the fact that the size of the social unit to which adolescents belong affects the potentialities for education inherent in the school. If the social and emotional development of the individual are as important as the intellectual, then the individual must experience social adequacy from his contact with his school association. He must have a sense of belonging, of imposing his will on the group at times, and also gaining reciprocal social values from the group. This is difficult in a school of several thousand pupils. As a result in some urban centers, a form of school organization is now coming into existence, referred to as a "school within a school". A pupil group of from 500 to 1,000 pupils has a separate administrative head, separate faculty, separate extracurricular program, separate social-civic existence. It is, however, part of a large administrative unit, sharing with other smaller groups certain parts of the school plant and school offering which cannot be provided effectively for each smaller group. Thus 5,000 pupils might well be housed on one school campus but have their intimate school relationships in from five to ten smaller groups, educationally independent of each other. Although this plan of organization is not yet general, it does exist in varying forms and is likely to become increasingly common.

Curriculum and methods. Originally the curriculum was solely college preparatory. In addition it was assumed that the subject matter acquired, irrespective of the method of learning it, was of sole importance.

With the advent of the academy (*q.v.*) movement a noncollege preparatory curriculum came into existence. In addition to the usual academic courses, architecture, biography, embroidery, civil engineering, law, vocal music, mapping, mythology, surveying, topography, and other "useful" subjects, deemed to be valuable to a pioneering people, found their way into the secondary school offering. The reaction of the college-minded group of educators to this hodgepodge of sub-

SECONDARY EDUCATION

ject matter brought the academic college-preparatory curriculum again into prominence during the last years of the 19th century.

Until this time the philosophy of method had not affected secondary education. It was not until the early part of this century that Hinsdale, McMurry, Parker and others introduced the ideas of Herbart and Dewey into the secondary school. Initially, and in fact until very recently, method was dealt with as an adjunct to curriculum. The learning of facts was regarded as the end of education. Method was simply a means of making the learning of facts more palatable and effective. This emphasis on method introduced such techniques and devices as the project and problem, socialized recitation, Dalton plan, the contract, unit organization, supervised study, homogeneous grouping (*qq.v.*).

Another movement affecting the curriculum is now in the process of evolving. The progressive elementary school with its concern about the child and his well-rounded development is leaving its impression on the secondary school. A number of influences have made this possible. Perhaps the one most immediately effective is that the college is no longer a static institution. For more than a decade it has been increasingly responsive to influences other than tradition. College admission requirements have been liberalized. This fact lessens the effectiveness of the secondary schools' contention that a certain prescribed curriculum for all academic (college preparatory) pupils is *sine qua non*.

The Eight Year Study (*q.v.*) of the Progressive Education Association has helped still further the progressively minded secondary school to throw off its yoke of college admission requirements. This study also has encouraged curriculum experimentation in secondary schools. As a result, new curriculum patterns other than that of the traditional academic subject-type have come into existence in various parts of the country. The direction of this movement toward a new secondary school is not yet so clear as is the form of the new elementary school, but it seems quite likely that basic changes are in the making. The emerging high school no doubt will be more directly concerned with youth's adjustment to the world in which he lives.

This change in emphasis, from subject matter as the end of education, through the use of appropriate devices or method to make subject matter learning more effective, to the concept that the end of education is the growth of the individual, has been aided and abetted by studies of the adolescent. The more we know about the characteristic of the adolescent the more we become aware of the shortcomings of a subject-centered curriculum and the more we become inclined to favor an experience curriculum (*q.v.*), and when this transition has taken place method can no longer be thought of as independent of curriculum. The two fuse, and method as an entity disappears. Secondary schools are now experimenting with various forms of integrated curriculums. The core curriculum (*q.v.*) and the unified curriculum are emerging. They have hardly begun, however, to replace the compartmentalized subject curriculum, which is the traditional pattern for secondary education.

Guidance. When secondary education first became conscious of its function to prepare for vocations, vocational guidance as a process came into existence. When emphasis on proper educational orientation within the school came to the fore, educational guidance was thought important. When the social character of the adolescent became recognized as a concern for the secondary school, social guidance was born. Thus gradually the concept of guidance was broadened until today, at least in principle, it is practically synonymous with good teaching.

When education was thought of as adjustment of the individual to a static or authoritarian standard—college preparation, as a body of subject matter to be learned, and as fixed skills to be attained—the guidance counselor became the functionary whose duty it was to help an unadjusted individual to a greater degree of adjustment. He therefore assumed the important role of supplementing the effort of the teacher, who was working within the framework of a fixed curriculum, in helping the pupil to attain the objective set for him by the school.

When, however, the curriculum changed its emphasis from the subject to the adolescent and his growth as the end of education, the place of the guidance counselor changed. If he was needed at all, it was in a consulting

SECONDARY EDUCATION

and advising capacity and not as a separate functionary.

Control. As the secondary school expands its concept of the function of secondary education it reaches beyond its four walls into the community and the world at large. The youth who leave its doors and enter the world of the adult but who find this world forbidding to them are returned to the community unadjusted, or they roam about the country in search of security. Before and even during the depression of 1932-36 the secondary school concluded that these adolescents were no longer their concern; but they became a national problem and therefore a national concern. The federal government implemented N.Y.A. (*q.v.*) and C.C.C. (*q.v.*) functionaries to cope with the problem. These were financed, controlled, and conducted by the federal government.

Increasingly, the local secondary school has become aware of its responsibility in this matter. Opposition to the federal usurpation of what have been assumed to be the rights of the community and the state has been raised. The community feels that it would be able to handle the problem adequately if the money spent by the federal government were made available to the local school district.

Some educators, however, point to the fact that secondary education is still too largely concerned with the traditional pattern of imposing an authoritative compartmentalized subject curriculum. They also point to the lack of provision made by the secondary school for vocational, social and civic rehabilitation. Private and quasi-public institutions have come into existence to take care of social and economic misfits. These operate independently of the school in most cases. In other words, the secondary school discharges its responsibility to society by giving youth a diploma, which in many cases is meaningless when measured by the needs of society. The private and quasi-public welfare organizations salvage those whom society has not been able to absorb effectively.

Until secondary education expands the concept of its obligations to youth and to society so as to include what must be corrected by the federal government as well as by local social agencies, it cannot be given exclusive control of the educational responsibility to youth. Progress in this direction has been

made. Some secondary schools sponsor community welfare projects, conduct comprehensive programs of adult education, and even cooperate in parent education programs through the organization of nursery schools as experience laboratories for older youth. But when accomplishment is compared with need, a beginning has hardly been made.

Various suggestions have been made to cope with the problem. Perhaps the one offering greatest possibility for success is the establishment of a community advisory council consisting of representatives from the existing welfare organizations interested in youth and of citizen groups which are touched by youth in some form—home, church, industry, labor. If such a council would look realistically and efficiently at the problem of youth and the effect which his adequate adjustment has on the welfare of society, the community could be trusted with the responsibility for the control of secondary education. Until this is done, large divisions of civic life must exercise control to avoid emergencies such as existed in the decade preceding World War II.

The future. The post war period will no doubt see many changes in our concept of secondary education. Now that secondary education for all youth is the responsibility of the state, society must revise its concept of the aims and functions of its educational responsibility to youth. Such questions as the following will receive increased consideration:

1. Must secondary education insure constant vocational competence to the members of society? In periods of depression or vocational displacement, must the secondary school provide the means for vocational rehabilitation?

2. What must be the concern of secondary education with regard to other areas of life—economic, civic, parental, avocational, social? Must competence in these be assured in proportion to individual ability and the current needs of society? For example, if freedom from want is an objective of democratic society, does secondary education have an obligation to insure that each individual can use effectively the economic resources which society can make available?

3. Must secondary education insure that all youth are imbued with the democratic way of life so that democracy as the natural pat-

SECONDARY EDUCATION, COMMISSION ON REORGANIZATION OF

tern will be protected and constantly improved? In other words, is indoctrination of democracy—as fascism, nazism, and communism are implanted in the youth of certain other countries—an essential responsibility of secondary education? If so, how is this to be done so that proper regard is given to individual differences to insure that a maximum degree of self-realization will be satisfied?

4. If secondary education at public expense and for national welfare is accepted, shall responsibility for control and support continue to be vested in the state and locality, or shall larger support and control be placed in the hands of the federal government? In other words, are projects like the NYA and CCC the prerogative of the local school, or must the federal government oversee such projects to insure equality of opportunity and responsibility for all?

SECONDARY EDUCATION, COMMISSION ON REORGANIZATION OF (National Education Association). This commission was appointed in 1913 by the National Education Association to look into the growing criticism of the college preparatory emphasis in the high schools resulting from the report of the Committee of Ten made twenty years before, or, as expressed by the then Commissioner of Education P. P. Claxton "to collect the best opinion in this country in regard to the aims and methods that should prevail in secondary education."

The creation of the Commission was stimulated by the report of another committee appointed by the N.E.A. in 1911 (Committee on Articulation of High School and College). This committee took the position that "the

satisfactory completion of any well planned high school curriculum should be accepted as a preparation for college."

Many reports dealing with the reorganization of courses of study and curriculums were made by it and its several subcommittees. These appeared as U. S. Bulletins from 1913 to 1922. The most frequently cited is the U. S. Bulletin, 1918, No. 35 presenting the Cardinal Principles of Secondary Education (q.v.).

Besides reports on each of the several subjects offered in secondary schools (English, social studies, science, music, home economics, etc.), studies dealing with moral values, part time education, vocational guidance, and high school building and grounds appeared under the commission's sponsorship.

Although much of the commission's pronouncement became controversial and did not have the immediate effect on school practice which was hoped, its accomplishments were far reaching in that they provided a new orientation for secondary education—away from the concept "what is good for college is good for life" toward the concept that preparation for living is insured through a program of education which encourages "complete living". (See SECONDARY EDUCATION.)

SECONDARY SCHOOL CURRICULUM, COMMISSION ON THE (Progressive Education Association). A commission established by the Executive Board of the Progressive Education Association in 1932. The need for such an organization grew out of the work of the Commission on the Relation of School and College, which was organized by the Progressive Education Association in 1930. In studying the relation of secondary schools to colleges, this commission felt the need for a more thorough analysis of the meaning and function of secondary education. The Commission on the Secondary School Curriculum was established to make an intensive survey of this special area, its chief purpose being to develop a program of research and planning that would clarify some of the basic problems of secondary education. Focusing its attention on the educational needs of all classes of youth, it was to suggest ways and means of studying the present curriculum and of evaluation how well it

met the needs of youth; and was to conduct experimentation in curriculum revision. The Commission analyzed the social values and purposes which operate in our society, did experimental work in selected schools where curriculum changes had been made, and, through various study conferences and curriculum workshops sponsored by the Progressive Education Association, studied the problems involved in making curriculum changes. To achieve its objective, the Commission selected two general approaches to the problem: (1) a study of adolescents and their problems from the point of view of the development of personality, economic responsibility, and social relationship, (2) a study of each of the major subject areas such as art, science, language, mathematics, etc., and of the way each area can contribute desirable educational experiences to the curriculum of the youth attending the secondary schools.

To facilitate this task several committees were established, one for each of the major subject matter areas and one for the study of the adolescent personality and development. Reports of these committees have been published from time to time, giving accounts of their procedures and findings. There is no general report of the entire Commission, but the publication *Reorganizing Secondary Education* serves as a key to the more specialized reports of each committee. This book, written by three members of the Commission, sets forth the common basic approach and philosophy of the Commission, its procedures, and the general findings resulting from its work.

The committee that was organized to make a study of adolescents consisted of educators, psychologists, physicians, sociologists, anthropologists, psychiatrists, and social workers. It gathered data directly from high schools and colleges, both public and private, in all parts of the United States. By collecting case histories it sought to discover information about adolescents which would give some insight into their behavior, maturation, and development.

The committees in each of the subject fields made a study and an analysis of their respective subject areas to determine their function in a program of general education. The findings and recommendations of these committees are reported in one or more of the publications listed below.

The commission suggests that (1) any reorganization in the program of the secondary schools should be based on the needs of young people; (2) desirable goals for a secondary school curriculum are to be found in the concept of the democratic way of life; (3) the rigidity of college entrance requirements tends to maintain the present emphasis on subject matter and subject courses in the high schools; (4) the broad subject areas such as science, social studies, art, etc., should be retained in the curriculum. E.O.N.

SECONDARY SCHOOL STANDARDS, COOPERATIVE STUDY OF. One of the difficult problems that have perplexed American education for several generations has been the articulation of the various levels of schooling that compose the American educational ladder (*q.v.*). While considerable difficulty was encountered in effecting a close tie between the elementary and the secondary schools, the transition between the twelfth grade and the first year of college presented greater complications. The former problem was met to some extent by the reorganization of secondary education, particularly with respect to grades seven to ten inclusive. The latter problem proved more difficult because areas not subject to unified controls were under consideration. (See ARTICULATION.)

SECONDARY SCHOOL STANDARDS, COOPERATIVE STUDY OF

It is interesting to note that all of the attempts at improving the work of the high schools have been in terms of the framework of local control. One of the chief devices for determining the adequacy of preparation of the graduates of high schools was the entrance examination imposed by the colleges. The gradual elimination of this procedure in most parts of the country became a responsibility assumed by secondary and collegiate leaders over a number of decades.

As long ago as 1871 the University of Michigan dropped the plan of entrance examinations in favor of entrance from certified high schools. It became the first agency for the evaluation of the high schools that supplied its freshmen. The principle was later adopted by a number of the colleges. Leaders in the secondary schools and colleges improved this program by organizing regional bodies known as associations of colleges and secondary schools. Over a period of time six associations were formed: The New England Association, The Middle States Association, The Southern Association, The North Central Association, The Northwest Association, and The Western Association. Some of the associations became accrediting agencies. (See ACCREDITING.) The New England and the Western Associations did not enter the field of accreditation. In the main, all of the associations gradually extended their interest to a consideration of all the problems common to secondary schools and higher education.

In the 1920's various leaders of the associations began to think in terms of constructing educational instruments to apply to the high schools so that a number of purposes might be served. One of these naturally was the relation between secondary schools and colleges. The problem had in it a number of possibilities for much wider areas of application than a simple measure of the worth of the graduates of high schools. Accordingly, a group of representatives of all the associations was formally organized in 1933. It became known as the General Committee and it posed the following questions:

What are the characteristics of a good high school?

What are the practicable means and methods to be employed to evaluate the effectiveness of a school in terms of its objectives?

By what means and processes does a good school develop into a better one?

How can regional associations stimulate secondary schools to continuous growth?

Realizing that a formidable task lay before it, the General Committee organized a full-time staff of specialists to work upon the devices that would indicate answers to the questions proposed. The experiment was labeled the *Cooperative Study of Secondary School Standards*. The work of building appraisal instruments that had validity and reliability involved a period of six years.

The staff, supported by funds advanced by the associations and by the General Education Board, and with the advice of leading educators, formulated eighteen bases for the consideration of secondary education. Out of these bases evolved a number of comprehensive and flexible criteria to evaluate the high schools at both junior and senior levels. Two hundred secondary schools of all types were selected for the purpose of trying out the early tentative forms of the measures. These were designed to be applied to the following areas: philosophy and objectives of a school, pupil population and school community, curriculum and courses of study, pupil activity programs, library service, guidance service, instruction, outcomes, school staff, school plant, and school administration.

The procedure adopted in applying the measures to a school was a unique one for American education. When a school leader made it known that he desired to have his school evaluated, all the necessary forms were sent to him well in advance of the time of the evaluation. He then set up a number of faculty committees to study the forms and to prepare the answers. In a number of instances the preparation of the forms covered a period of months. At an agreed time, a committee of educators, generally about ten to fifteen in number, came to the school. As a rule, they represented other school systems, the state department, and some of the colleges. The visitation period covered from two to four days, depending upon the size of the school. The committee examined the self-evaluations that the faculty committees had made and observed the educational processes in the school. It has been stated by those who have taken part in the evaluation procedure that the most important work of the whole

SECONDARY SCHOOL STANDARDS, COOPERATIVE STUDY OF

process had been carried out just before the visiting committee made its appearance.

The visiting committee was organized into working groups which were charged with the careful examination of the faculty reports. Near the close of the time involved in general visiting throughout the school, the visiting committees met with the faculty committees who had prepared the reports in order to be certain that mutual understanding existed regarding the reports. Another novel feature of the visiting committee procedure was a meeting with a group of students selected at random throughout the school. The purpose of the gathering was to observe the type of student present in the school and in a friendly fashion, to get the students to give reactions to the school procedures.

The head of the school, shortly after the departure of the visiting committee, received in graphic as well as in written form a report upon the work of the school. Frequently a number of the evaluations set up by the faculty committees were revised downward because many schools thought they were better than they actually were. The graphic scheme of reporting was another unique device constructed by the cooperative study directors. It consisted of a series of graphs fashioned after an ordinary thermometer. Along the sides of the thermometers were symbols which showed where a given type of school in any one of the six geographical regions would normally register. Each of the school areas mentioned earlier was described not only by a number of these thermometers, but also by one that showed the total cumulated and weighted score for the whole area.

The report of the work of the visiting committee to the principal became more often than not the inspiration for many faculty meetings. The purpose of such meetings was to examine the findings of the report and to suggest means by which the weaknesses of the school might be overcome. These meetings were often stimulating and frequently brought out the fact that many persons regarded the whole evaluative procedure as an outstanding educational experience.

Some of the results of the cooperative study were important for secondary education. School staffs became conscious of the necessity for a well stated and comprehensive philosophy of education for their particular

schools. The application of the measures proved a valuable in-service training means for all educational workers involved. Renewed and awakened interest in the problems of the schools, stimulated by the findings of the visiting committee, often found suitable outlet in series of professional faculty meetings, department meetings, and the like. By virtue of the organization of the faculty committees, departmental isolation was broken down and the school staffs worked together on schoolwide problems—a situation that promoted esprit de corps. Many leaders in colleges, state departments, and local school systems came to know and appreciate each other through the work involved in appraising a school. On the whole, in those sections where schools were evaluated secondary education was stimulated to greater efficiency in terms of a modern educational program.

The Cooperative Study of Secondary School Standards has not been applied universally. Although Colorado, Indiana, Kansas, Maryland, Ohio, and other states have manifested considerable interest, as evidenced by the schools evaluated, a number of states still have many schools that have not participated in the experiment. (See EVALUATION.)

SECRETARIAL EDUCATION. In the early days, secretarial education, both in the high school and in the private business school, was concentrated largely in the areas of shorthand, typewriting, bookkeeping, and grammar. Shorthand and typewriting were taught as separate subjects with little effort to develop transcription ability. Shorthand was almost exclusively taught by the deductive method with emphasis on copy-book perfection of outline rather than on facility of execution. To accomplish the objective of perfect outline, repeated practice on isolated words was generally used. The careful execution of individual outlines was later speeded up by dictation of context material. The publication of the Functional Method of learning shorthand turned attention of teachers to the possibilities of mastering shorthand by direct association.

Similarly, in typewriting the emphasis in elementary instruction was on the slow and accurate learning of isolated keys. Later in the course "speed practice" was begun. Present trends in instruction in both shorthand and typewriting are toward the fluent and rapid use of the skills, rather than upon accuracy of knowledge. The general tendency is toward integrated rather than analytical instruction.

Shorthand and typewriting in the high school were often taught as early as the ninth grade and continued through the four years. Recent tendencies in curriculum construction usually place the two subjects in the eleventh grade, with the idea that secretarial workers need to have their skills developed to occupational levels of competency at the time they leave school. It is also considered necessary that the secretarial worker have a good background of general education and of nontechnical business education.

The course in secretarial practice has been added to the curriculum. This course has for its purpose the integration of all the student's

secretarial learnings in a situation approximating as nearly as possible actual office employment conditions. It is in this course that such additional secretarial abilities are developed as voice-writing-machine operation, filing, and receptionist duties. Transcription training is becoming an increasingly integral part of secretarial education.

The upgrading of the specific secretarial subjects in the high school has been accompanied by an increase in the number of colleges, junior and senior, offering secretarial education on a two-year or four-year basis. The employment demands for more mature persons to fill secretarial positions, together with the relative lack of employment opportunities during the period 1930 to 1940, served to develop this trend. These factors, as well as the fact that the high school secretarial course has had unprecedented popularity with students, resulting in the enrollment of large numbers of unselected students in secretarial curricula, have served to establish somewhat the point of view that the high school prepares only for initial stenographic positions.

The private business school and the college are regarded as especially well adapted to educate secretarial workers. The private school, first in the field of secretarial education, has continued to render a valuable service in complementing and supplementing the education offered by the high schools and colleges. SELF-CORRELATION. Literally *self-correlation* is the correlation of a test or variable with itself. Traditional methods accomplish this by one of three procedures: (1) test-retest method, in which the same test, same form, is given in succession to the same group, with an intervening time between tests; (2) alternate-form method, in which two comparable forms of a test are administered to the same group; and (3) split-half method, in which the test is arbitrarily divided into two comparable halves and two scores obtained for every individual. The favorite way of obtaining comparable halves is the odd-even division—odd-numbered items in one half, even-numbered items in the other. More recently, procedures based on the inter-correlation of items themselves, which tend to avoid objections generally leveled at other methods have been elaborated by Kuder and Richardson. (G. F. Kuder and M. W. Richardson, "The Theory of the Estimation of Test Reliability," *Psychometrika*, 1937, 2, 151-160.) The goal of these procedures is to find an estimate of *reliability* (*q.v.*) of the test or measuring instrument. The self-correlation of a test is taken as its measure of reliability. J.P.G.

SELF-EDUCATION. Any effort made by an individual for the conscious purpose of improving himself in knowledge, understanding, skill, habit, attitude, or ideal. Purposeful reading, self-instituted and directed exercise, attendance upon lectures or musical concerts, visits to museums, conscious and planned improvement of personal qualities are among the countless avenues of self-education. Self-education should be distinguished from ordinary play or recreation in that it has a definite educational purpose and is not just a matter of enjoyment. Self-education should be distinguished from school education in that it is self-instituted and self-motivated. Both of these distinctions are, of course, not absolute but matters of degree. Obviously, there can be both fun and self-motivation in formal school-directed education. Efforts at self-education have sometimes been labelled "self-improvement," and, as such, have been seriously questioned by educators and psychologists. The criticism has been directed chiefly at priggish and unrealistic attempts at the improvement of broad traits without regard to the fact that traits

arise as the integration of many specific actions. Consequently, the success of self-education depends upon (1) an educational goal defined in terms of specific ends to be reached, (2) strong motivation, (3) definition of things to be done that the individual *can* do and that are related to his goal, and (4) active effort by the individual. SELF-GOVERNMENT. Any plan of school administration which provides that pupils participate in the government of the school may conceivably be labelled "self-government". There are few, if any, schools, however, in which the pupils are entirely self-governing. In elementary schools the most common plan of self-government involves: (1) room organizations, with each room having its own officers, (2) a school council of room representatives and teachers, (3) school officers, usually elected from the upper grades. Secondary school student government usually follows a similar pattern with the home room being the smallest representative unit. In colleges the student council is more apt to be made up of representatives from the various clubs and the class organization. This type of student council is also found in some secondary schools. Sometimes the type of organization has been patterned after the national, state, or municipal government, as in the "School Republic", which was first organized in a New York City school in 1896 by Wilson L. Gill. Such elaborate organizations have not proved as useful as simpler systems adapted to local need.

In almost all schools having some form of self-government, every student is automatically a member of the school student body and entitled to participate in the government of the school to the extent provided for by the plan in his school. It is generally understood that the powers of student governing bodies are delegated powers. In fact this is explicitly stated in many student council constitutions. Ultimate responsibility and authority lie with the head of the school—principal, president, or governing board.

What a student government organization does, depends upon the extent of authority delegated to it, the quality of its leadership, and the peculiar needs of the school. Such

bodies frequently play a large role in the administration of extra-curricular activities. They usually participate in assembly programs, run class elections, stimulate student enthusiasm for athletic contests, arrange social affairs, and in many ways assist in the maintenance of morale. Frequently a student council deliberately sets out to change public opinion in the school, often at the suggestion of the principal. Fretwell¹ has given a "functional classification" of 114 student council activities.

Student participation in school government is justified chiefly on the ground of its educational values, especially in the training provided in citizenship and the development of leadership qualities. There can be little doubt also of the value of such participation to those responsible for administering the school. The school runs more smoothly for the good spirit and work of the pupils when they have a part in its operation.

The limitations and dangers of pupil-participation in school government are: (1) Exploitation of students by school administrators. It is possible to pervert a student government organization to an administrator's ends. (2) Inadequate training of students in the choice of leaders. Election of the school hero to responsible position, regardless of his ability, is an example of this danger. It can be offset by proper education. (3) Failure to define the source and the limits of the student government's authority. (4) The tendency for student government to copy the worst rather than the best features of political life. (5) Impatience with democratic procedures, especially on the part of school administrators. These dangers are all subject to control.

The success of pupil self-government depends largely on the degree of enthusiasm and vision of the principal and teachers. A plan of pupil self-government should be viewed not so much as an administrative convenience or inconvenience but as an opportunity, at the cost of time and effort, to give children the experiences that will help them to gain an insight into the needs and values of democratic processes. (See STUDENT COUNCIL.)

SELF-MARKING (TEST PROCEDURES). Accuracy and speed of scoring may be markedly increased by making use of automatic scoring devices. Tests using self-marking techniques are so arranged that correct responses are readily compared with an accompanying key, which is hidden from the subject. Thus, one popular self-scoring device uses carbon paper to transfer the subject's response (an X in one of five squares) to the key sheet, which shows the position of the correct answer by a small printed square. The subject's score is then easily computed by counting the number of squares on the key sheet in which there are X's. Another device requires the use of a stylus. The subject is asked to indicate his choice of answer by making a pin hole in one of a number of squares. At the same time, he makes a pin hole in the key sheet, which is placed under the answer sheet. The correct answer is indicated on the key by means of a single square in the appropriate position. The subject's score may then be computed by totaling the number of squares on the key sheet which have pin holes in them. J.J.

SEMANTICS IN EDUCATION. Semantics is that phase of the study of language which is concerned with the meanings of words. As the meanings of words include all the ideas and feelings that men have ever expressed and all the external objects and events they have ever discussed, the scope of semantics is vast. Theoretically, it comprehends every branch of human activity which is related to language; and one of the significant characteristics of twentieth-century thought has in fact been the attention paid by students in many different fields to the semantic aspects of their subjects. As C. W. Morris points out in *Foundations of the*

SEMANTICS IN EDUCATION

Theory of Signs, "It is doubtful if signs have ever before been so vigorously studied by so many persons and from so many points of view. The army of investigators includes linguists, logicians, philosophers, biologists, psychopathologists, aestheticians, and sociologists."

In practice, however, students of semantics have found it impossible to explore the meanings of words in their entirety and have limited themselves to the study of certain relationships between words and the meanings they express and communicate. They have been especially concerned with studying the relationships between words and ideas; words and external reality; various meanings of the same word; the meanings of words and the contexts in which they are uttered; words and the neurological activity of the individuals who use them; and words and the social activity of human groups.

The four schools of semantic thought which have probably been most influential in modern education are (1) the general linguists, (2) the mathematical-physical theorists, (3) the school of I. A. Richards, and (4) the school of Alfred Korzybski. (1) Students of general linguistics have been most concerned with the historical aspects of semantics. They have traced the socially-accepted meanings of words as these have changed through history and examined the semantic relationships between one language and another. Their emphasis has been on etymology; they have studied "vocabulary in motion," and stressed the fact that meanings are not static but in process of change. This emphasis is expressed in dictionaries organized to show changes of meaning, notably *A New English Dictionary on Historical Principles*. (2) Mathematical-physical theorists have been especially concerned with the problems of limiting the meanings of words so that they will be stable for purposes of scientific communication. Recognizing that meanings are normally psychological events and that vocabularies are "in motion," they have sought devices to objectify meanings. One such device is the formulation made by P. W. Bridgman of "operational meaning," that is, the assumption for scientific purposes that the meanings of certain terms are only certain specific and observable actions, and that any other responses to these words are to be regarded as irrelevant. (3) I. A. Richards and his

followers have made a special science of meaning and its interpretation. Emphasizing the symbolic nature of words, they have stressed the fact that words are capable of conveying a multiplicity of meanings, that any particular meaning depends upon the context in which the word is used, and that the proper interpretation of meanings necessitates an awareness of the subtle and inter-related way words work. (4) Alfred Korzybski and his Institute of General Semantics have called attention to the close relation between language and the psychological activity of the individual nervous system. Discarding the term "meaning" as inadequate, Korzybski has described words as the semantic reactions of human beings and insisted on the close correspondence between (a) the symbolic picture or evaluation of the external world which is implicit in the words one uses and (b) one's actual adjustment to the world. To distinguish his system from a mere study of etymology or of isolated word meanings, he has called it General Semantics.

Students of semantics are agreed in viewing words not as static entities but as phases of human activity. Words are to be sharply distinguished from that which they symbolize, as the word "dog" is not the same as an actual canine. The fact that dictionaries can record verbal definitions of words is useful, but may be misleading if one does not understand how dictionaries are made. The reality of verbal meaning is to be found, not in the word itself, but in the symbolic activity of the human nervous system. This symbolic activity may or may not communicate an accurate picture of that which it attempts to symbolize.

The influence of semantics on American education began to make itself felt definitely in the 1930's, not as a new subject in the curriculum, but as a new emphasis which affected many subjects. In general, it brought an increased sense of the importance of language together with a heightened sense of the dangers of verbalism. Teachers of reading put less emphasis on isolated words and phrases and more on the relationship between meanings and the experience of the reader. Teachers of composition increasingly viewed language growth as closely related to the development and expression of real meanings in the experience of the child. Teachers of mathematics saw mathematics as a type of

linguistic behavior and helped students to analyze the assumptions implicit in mathematical terms. Teachers of social studies helped students to understand the semantics of propaganda. Especially in the colleges, there was a revival of interest in rhetoric. Early in the 1940's a number of teachers and institutions, notably the Institute of General Semantics, reflecting Korzybski's point of view, and the Orthological Institute, reflecting I. A. Richards', were developing teaching materials for direct instruction in semantics; but the most important educational influence of semantics up to that time was indirect.

SEMINARS. Seminars developed in American higher education with the advent of graduate study and research, probably in the 1870's. They are small, informal groups of not more than perhaps twenty students with one or more professors, usually assembling not oftener than twice a week. Their main purpose is to provide unhurried, intimate discussion of advanced study by professors and students specializing in the same field. Frequently they are used for preliminary discussion of thesis subjects being studied for graduate degrees. They are also used for instruction in research techniques, for discussion and study of a professor's research or special interest, and incidentally for social purposes. Since they are small, their procedure and atmosphere tend to be informal. Curriculum

credit is usually, if not always, given for them. While most of these characteristics are almost universal, seminars vary in detail from university to university and from department to department.

Seminars have been used also for upper-class undergraduates, especially in honors plans. There they retain their characteristics of informality, discussion, specialization, and individual study.

Seminars have all the benefits of small-group instruction, and have been the forerunner of plans for informality and individualization in college instruction, as well as of discussion groups, workshops, and the like.

M.G.F.

SENSE REALISM—See REALISM.

SENSE TRAINING. The necessity for training the senses has been emphasized by psychologists of widely differing views regarding sensation, perception, knowledge, and the relation of these to each other. Whatever the difference in theory, there is agreement that sense training must result in the ability to make finer discriminations with respect to shape, size, sound, rhythm, odor, weight, brightness, color, feel, distance, etc., and in the attaching of valid meaning to sensory impressions or perceptions. It has been found that verbal learning without a background of direct sensory experience remains meaningless and unusable to a great degree. Equally inadequate are such formal exercises for the training of sensory discrimination as are used in some kindergartens.

The best training arises when the child meets situations in which sense discriminations are necessary for the attainment of his purposes. In the ordinary course of living, the child gives himself a good deal of such training. Adults can help by providing the child with a wide variety of material for his exploratory and creative play activities and by widening his physical environment to include more and more kinds of indoor and outdoor experiences.

Growth in the fineness of discrimination does not proceed evenly for all the senses. It is a general principle, however, that rough outlines of wholes are perceived before details are discriminated and that fine discrimination has as much to do with interest as with sense acuity. Thus a mother who can

discriminate between, and attach the proper meaning to, different varieties of her baby's crying may be unable to distinguish the various sounds of different motors which a mechanic can differentiate immediately.

In the case of the physically handicapped, where the sense most commonly depended upon for meaning cues is deficient, another sense must be trained to get these meanings. The deaf use the visual cues of lip-movement to understand what another person is saying, and the blind use touch cues in the reading of braille. The abilities which sensory-handicapped persons develop only emphasizes the fact that sensory discrimination improves most as the need for finer discriminations arises.

It may be difficult for the teacher of today to realize that at one time educational controversy was concerned not only with regard to how sensory discrimination can be made more acute and how ideas are related to sensory experience, but also with the question of whether the senses need enter the educational process at all. For centuries the schools were concerned primarily with words, and the reading and imitation of the Greek and Latin classics and of religious literature.

The actual use of observation and sense perception was an innovation recognized as such in the sixteenth, seventeenth and eighteenth centuries, for it was a long time before the movement took hold in education practice. From Francis Bacon's rediscovery of the method of science and his emphasis on the inductive study of nature as the foundation of education, and Comenius' method of learning through observation, to Pestalozzi's denunciation of verbal rote memorization and his advocacy of object-teaching (*q.v.*), to Herbert's systematic formulation of an inductive-deductive pedagogic method which included sensory perception as a basic element, to John Dewey's emphasis on experience as the foundation of education—this was a very long period indeed. Yet, in spite of the pragmatic nature of science and the prestige which science holds in the modern world, teachers are still largely depending upon verbal techniques, and the experience curriculum, still known as the "new education", is having a difficult time to do more than just edge its way into the majority of schools. SERVICE LOAD — See PUPIL-CLOCK-HOURS; TEACHER LOAD.

SEX DIFFERENCES. The term *sex differences* is used in psychology with reference to differences between the two sexes, considered as groups, in various traits and behaviors. The term is applied equally to differences that are innate and to those that are mainly or altogether due to pressures of the culture. An analysis of the origins of the sex difference as found must be made for each specific type of difference. Studies of young children, of persons at various age levels, of groups in various parts of the country and in different countries and cultures and periods of time are all needed to determine the extent to which the difference is biologically conditioned, so that it will not lend itself to environmental modification. Reported differences are usually in terms of a comparison between the averages of each of the two sexes, though range and distribution may also be compared. On the biological side stands the fact that girls mature physically more rapidly from birth to adolescence than boys. Girls, on the average, walk and talk earlier than boys, and in childhood their size and strength is equal to that of boys. It is in adolescence that great divergence between the two sexes in size and strength begins to take place and the girls, as a group, fall behind the boys in any activity which involves large muscle work, though still maintaining a lead where small muscle coordination is needed. More boys seem to be left-handed, and color blindness among males affects, according to varying estimates, from four to seven per cent, while it is less than one-half of one per cent in females.

With regard to general intelligence, numerous studies show that there are no reliable sex differences in average intelligence quotients of large groups of school children. There are differences, however, on parts of the test. With regard to both younger and older age levels, the girls are better in the verbal parts; the boys, in the mathematical. In tests of memory, the girls are also slightly ahead. It is important here to emphasize that when a *significant difference* (*q.v.*) is reported, it does not mean that the difference

SEX DIFFERENCES

is significant in terms of its size. In these instances, the term *significant* is used in a statistical sense and means *reliable*, with no reference to its importance. A very slight sex difference of no import whatsoever may be a "statistically significant" difference. Furthermore, in applying the concept of sex differences in education, the great overlapping in distribution of the two sexes needs emphasis. Because of this overlapping an individual cannot be characterized with respect to a given trait simply on the basis of his sex membership, but he must be examined as an individual with respect to that trait. Bearing this in mind, we can look at differences which have been found with regard to school achievements. In general educational progress, girls are ahead of boys in all grades from the primary grades of the elementary school through college, though the difference is least in college. Boys have been reported as being better in arithmetic, nature study, science, history, and literature; girls are reported as superior in reading, language usage, spelling, handwriting, and art. College men have been reported as superior in mechanics and science; college women, in arts and letters. The fact that at one time boys are reported as being better in literature and at another time that girls excel in arts and letters, is a warning that generalizations derived from specific test differences must be made very carefully. One generalization that has been made repeatedly is that girls are better when quickness or speed of adaptation is required; boys, when reasoning is involved. In the field of attitude and emotion and interest, the divergence from adolescence onward is often marked. While studies of American preschool children have shown no sex differences in sympathy, women are commonly more expressive of active sympathy than men. They are also more ready to talk about their emotions and to confess their weaknesses. How much this is owing to glandular changes due to sex maturation, and how much to cultural traditions cannot be determined. In our culture as in other cultures, distinctions are early and forcibly drawn between the socially acceptable activities and attitudes for males and females. These cultural conventions may even be in large measure responsible for the boys' superiority as a group in arithmetical ability and mechanical aptitude. Studies

made by the anthropologists among primitive groups show that occupational interests and such social attitudes as aggressiveness and submission may be distributed in contrary ways in different cultures.

The rôles of the sexes in society is a central force playing upon boys and girls from early childhood. "This is for girls," "This is for boys," "This is sissy", "This is tomboyish" are some of the earliest judgments, restrictions, and encouragements placed upon children's behaviors. Sex differences may be created where none would occur as a direct result of constitutional sex differences, while slight differences may be widened enormously. Even when discriminations are legally or officially removed, the mores may continue to carry the sex traditions for several generations and produce almost as great a sex difference as heretofore. The educator is thus faced with both a challenge and a problem. The problem is one of determining in the light of present social trends and future indications, what attitudes, abilities and interests it would be best for each of the sexes to acquire. The challenge is one of seeing that differences are eradicated or widened in the light of what would make for the best social adjustment.

Educators have had numerous opportunities in recent years to see how easily modifiable are some of the interests and abilities which have been regarded traditionally as indicative of differences between the sexes. When classes in household arts are opened to boys as well as to girls, many boys are as interested and as competent in that subject as are the girls. Similarly, increasing educational and vocational opportunities for girls reveal that many girls are as interested and as competent in mechanical operations as boys are.

Some of the laymen's, and even the teachers', fallacies concerning the degree of sex differences in interests and abilities stem from a misinterpretation of the results of such investigations as have been conducted. When boys are reported as being superior to girls in arithmetic, it is easy to conclude that all boys are superior in arithmetic to all girls. Though the investigator spoke only in terms of average scores for large groups of boys and girls, the layman applies the conclusion to individuals. The outstanding characteristic

SEX EDUCATION

of statistical studies of sex differences is the great degree of overlapping of abilities and interests that is revealed. Although the average score in arithmetic may be greater for the boys than for the girls, there are a large number of girls who are superior in arithmetic to the majority of the boys. So great is the overlapping of the sexes in the abilities and interests which enter into school experiences, that they afford the educator little guidance in planning a separate program for boys and girls. To be sure, the educator must continue to make appropriate adjustments for physiological differences and for differences in the rates of growth, as well as for the differences necessitated by current social and economic conditions. SEX EDUCATION. Sex education represents a society's attempts to help the child in three related ways. First, most children inevitably ask questions about matters of sex. Sex education involves efforts to answer these questions helpfully and sympathetically. Second, every well-adjusted person must achieve a wholesome acceptance of sex in its proper perspective in his life. Sex education involves efforts to lead the child to this balanced perspective. Third, in modern society the adult is expected to adhere to certain standards of restraint and of respect for others in his sex life. Sex education involves teaching the child to accept reasonable restraints and to fit his pattern of living into the demands of society.

The fact that there are wide differences of opinion about how these three goals should be achieved, in no way helps the individual child or relieves society of its responsibility for sex education. The motive for much sex education has sprung from concern over venereal diseases and their spread. There can

be no doubt that the currently growing frankness about the venereal disease problem makes intelligent sex education more possible. This concern for the physical results of illicit relations naturally tended to make the earlier efforts at sex education largely a matter of teaching the physical factors in sex and the dangers of illicit sex relations. In fact a good deal of the early sex education was a matter of trying to scare children into virtue.

More recently it has seemed that a broader approach to sex education is imperative. A number of conditions have pointed to this conclusion. One authority has listed six factors that have contributed to this concern: (5. p. 193) "(1) the new and freer position accorded to women; (2) the mobility which makes it easy to escape surveillance and to attain anonymity; (3) the development of prophylactic and contraceptive technics; (4) new points of view in psychology, especially the psychoanalytic studies; (5) the host of sex stimuli found in cinema, theater, advertising, popular magazines, and songs; and (6) differences of opinion on matters of conduct upon which there was once, whatever practice may have been, a practical unanimity". Clearly these conditions point to the fact that sex education must be broader than a smattering of physiology and morality. Sex education has become the concern of sociologists, economists, recreation leaders, teachers, and psychologists, as well as of physicians, clergymen, and parents.

Objection to sex education has arisen from a number of sources. Some church leaders have objected to any sex education other than that provided by parents and clergy, lest the child be taught sex ideas contrary to church doctrine. Similar objections to sex education in schools have come from parents who have held it to be their prerogative albeit there is ample evidence that parents generally neglect to give adequate sex instruction to their children. Educators have objected to being asked to provide sex instruction because they are afraid of conflict with religious objections and because there are few teachers adequately prepared by training, experience, and temperament to do the instructing.

There is fairly general agreement that an adequate program of sex education should include the following elements:

1. Careful and sympathetic attention to the

child's questions regarding sex whenever these questions arise. The child will show curiosity about sex in the pre-school years. Parents must be prepared to meet these questions. Most important is a sane attitude on the part of parents toward the child's curiosity and toward his early sex play. It is far more necessary that the child develop a wholesome attitude toward sex than that he be fully informed about the physiological aspects of sex and reproduction.

2. Adequate and stimulating opportunities for play and recreation throughout childhood and adolescence. Abnormal sex interest and perversions often arise from boredom, from nothing to do but to turn one's interest in upon one's self.

3. Reasonable attention to sex as a factor in the various subjects of school instruction. Sex is a social and psychological phenomenon, as well as a physiological fact. It should be given attention as an element in the study of social living and in literature, as well as in hygiene and physiology. There is no reason to believe that intensive sex instruction is desirable. Normal, unemotional recognition of sex as a factor in human living wherever it may be faced will supply the child's need for information in a more natural way without over-stimulating his interest in sex.

4. Provision of adequate guidance and competent counseling service for children in school and out. In adolescence, particularly, young men and women often feel a strong need for sympathetic counsel from someone other than their parents. This is true even when the parent-child relation is good.

5. Provision for parent education, both for secondary school and college youth and for parents. This should stress the whole range of parent-child relationships and family concerns.

6. Adequate programs of health and physical education. One of the powerful motives for a sane sex life can come through the appeal to the young person's concern for vigorous health.

7. Finally, there must be adequate social control of such sex-stimulating agencies as the motion picture, magazines, radio, advertising, and such commercial amusements as dance halls. The most serious efforts to provide constructive education will not be effective if the youngster is constantly subjected to demor-

alizing influences outside the home and the school. (See CHARACTER EDUCATION.)

SHOPWORK. As used by educators, *shopwork* usually refers to instructional work performed or given in school shops. Shop instruction may be general and prevocational in nature, as in industrial art shops, or it may be given on a vocational basis. Among the types of shopwork that are most commonly given on an industrial arts basis are woodwork, metal work, electrical work, and printing. The metal work is often general metal work. This means a combination of several kinds such as sheet metal work, pipe fitting, machine shop work and perhaps welding—forge, gas, or electric.

Vocational shop work varies more in type. In the all-day trade and industrial schools, machine shop practice, electrical work, auto mechanics, printing, carpentry and cabinet-making, and sheet metal working are very common. Some of the newer types of vocational shop work given in schools include aircraft repair, aircraft engine repair, air conditioning, battery service, Diesel engine repair, garment and needle trades skills, hotel training, instrument repair, linotype operation, lithography, marine engine mechanics, metallurgy, neon tube lighting, oil production and

refining, optical mechanics, police service, refrigeration, telephony, textile weaving, and many others.

In industry, the term *shopwork* is used for work performed in *production shops* or shops in which goods are produced; in *maintenance shops* or departments which concern themselves with up-keep such as painting, repairing and redecorating; and in *service shops* of various sorts, for example, radio, gas, or electrical service shops. (See INDUSTRIAL ARTS EDUCATION and VOCATIONAL EDUCATION.)

F.T.S.

SHORT COURSES. The term *short courses* has been used in both the industrial and professional fields to designate a type of course which attempts to give in abbreviated form a larger field of knowledge. The agricultural and homemaking colleges have generally made use of the short courses for both men and women. Such courses are usually offered at off-seasons and vary in length from one week to three or four months. The offering is in the way of refresher courses and those representing new materials and findings. In the trade and industrial world, short courses designed to give workers new skills, or to retrain them in new processes, form an important part of the trade training program.

Short courses also have been organized for professional workers. An example of this program is the continuing education center at the University of Minnesota. This center operates short courses, clinics, and conferences for doctors, lawyers, and other professional workers.

The heart of the cultural, economic, political, and social revival in Denmark was the Folk High School (*q.v.*), a short course program (five months for boys, three for girls). Such courses were operated during the winter months when young people from the rural communities could be spared from their home and farm duties.

The short course program is essentially an adult education technique. Its application in this country has been largely in technical fields, although there are beginnings in cultural fields.

SHORTHAND, TEACHING OF — See SECRETARIAL EDUCATION.

SIBLING RIVALRY. A feeling of conflict between children of the same parents which usually expresses itself in jealousy. It frequently begins in a young child when the new baby receives attention which was formerly his. Comparing children in the same family and showing favoritism also provide experiences from which this struggle for supremacy begins. Sibling rivalry is an important factor in developing emotional maladjustment in children which may prove the source of subsequent behavior or conduct problems.

M.S.Q.

SICK LEAVE. The majority of absences among teachers is caused by personal illness. Considerable substitute-teacher service must be provided in practically every school because of teachers' illnesses and maladjustments, illness in family, death in family, and other causes.

Absence regulations should be flexible in order to meet varying conditions; they must be specifically stated and clearly defined; they should protect everyone concerned; they should be simple in their application; and they should provide for an adequate system of records.¹

The flat-rate plan, whereby a fixed amount is deducted for each absence, takes care of the large majority of absences. The most frequent number of days allowed is ten. The average teacher absence is between six and seven days each year. This amount of sick leave, however, is inadequate for the occasional extended leave on account of personal illness.

The cumulative-leave plan, whereby the sick-leave days which are not used accumulate year by year, has increased in popularity during recent years. In a few systems the accumulation may go on for as long as ten years, but most school systems that use the plan set the limit from two to five years. This plan offers the teacher protection against the hardships of an occasional extended illness, but many of the characteristics of the plan condemn it. It guarantees nothing to the school board, but everything to the teacher. It does not protect the teacher who is new to the system. In some cases it has proved more expensive than other systems. When sick leave can accumulate, teachers may teach when they are really too sick to teach effectively because

they wish to save their sick leave for a more serious illness that may come in the future.

Under the flat-rate, fixed amount deductible plan, a number of days are allowed each teacher for sick leave. A small amount is deducted from the teacher's salary for each day of absence. This plan lessens malingering at the expense of the community, but unless the deductions are relatively large the number of absences is not appreciably reduced.

In many school systems the substitute's salary is taken out of the absent teacher's salary. This plan has obvious objections.

Under mutual-benefit plans, teachers insure each other against salary loss during illness. Payments are usually less certain than they are under the mutual-benefit, group-insurance plan. Both plans have proved to be inadequate.

Reeder reports a plan whereby a bonus system gives the sum of \$50 to each teacher with a perfect attendance record. Each day of disability absence costs the teacher \$5 of this bonus until it is consumed. This system obviously has the same limitations as other plans by which the teacher is "docked" for illness.² (See LEAVE OF ABSENCE and SABBATICAL LEAVE.) D.H.C. and A.R.A. References.

SIGNIFICANT DIFFERENCE. A difference, as that between mean scores for the experimental and control groups in an experimental investigation, is ordinarily said to be statistically significant if it is more than three times its standard error. A significant difference is one practically certain to represent a true difference greater than zero, apart from errors resulting from failure to obtain a random sampling. Thus, if an experiment to evaluate two methods of teaching stenography reveals a significant difference between the two methods, we are justified in concluding that the method which proved to be superior in this experiment would continue to be the superior method if the experiment were repeated with other similar groups.

The concept of a significant difference is often misunderstood by amateur statisticians

because the word *significant* has a statistical connotation that is overlooked. A difference may be statistically significant even when it is too small to have any real meaning to the educator. Thus, a new method of teaching stenography may be consistently superior to the traditional method—that is, the difference is statistically significant—but the superiority may be so small as not to justify adoption of the new method with all that may be involved in the purchase of new texts, the re-education of teachers, and the change in school organization.

While the statistical significance of a difference is an important factor in the evaluation of research results, administrators must also consider the practical significance of the difference when deciding what use should be made of these results. (See CRITICAL RATIO.) J.R.G.

SLOW LEARNER. The term *slow learner* is now applied not to those who are slow to learn this or that specific skill or area of information but to those who have obtained scores on intelligence tests which are below average (i.e., below normal) but above the upper limit set for the definition of mental deficiency. Children who range from 70-90 I.Q., estimated to constitute more than 20 per cent of the school population, are the ones most usually included in the category of slow learners, though for such practical purposes as the organization of special classes, lower limit of 75 I.Q. and an upper limit of 85 I.Q. are often used.

The two words of the term "slow learner" indicate that within the scope of their capacities these children are able to learn, though

their rate of progress is slower than that of the average child. Moreover, the slowness relates to the learning of meanings built upon abstractions and symbols commonly referred to as intellectual. The school subjects in which the "slow learner" is retarded for his chronological age are those which involve a good deal of reading and reasoning, especially reasoning with words and numbers or other symbols. These same children may do very well in manual work, artistic appreciation, and social adjustment. When dealing with the slow learner, the teacher must be aware of both the child's abilities and his weaknesses. It is unwise to make the child spend so much time in trying to improve at those points where the prediction is that he will always be inadequate that he has no time to gain a relatively high degree of skill in those areas where such a result is possible for him. It is of importance to know the kinds of procedures that will reduce the difficulties that slow-learning children have with verbal material. Many educators still recommend drill as the main technique for teaching those of below average intelligence. It is true that drill will produce faster results than other methods when evaluation is in terms of short, verbal responses to isolated questions of fact. It is equally true that such memoriter drill later results in speedy forgetting, or, at best, in the accumulation of bits of verbal knowledge which the child cannot use to any practical purpose because they have so little meaning for him.

Fundamentally, the slow learner learns in the same way that other children learn. In the Speyer School experiment⁴ it was found that the slow classes (75-90 I.Q.) and the very bright classes (I.Q.'s of 130 and over) both gained tremendously when learning started from concrete meaningful experiences and when the children could examine and use all kinds of materials. The bright children of course learned much more than the slow from the same materials, but the slow did their best learning not when they were drilled but when they were helped to understand and to work things out for themselves as much as they were able. In other words, an experience curriculum for the slow learner suited to their purposes is as important as such a curriculum for the bright.

One of the great needs for teaching slow-

learning children is verbal material that is not too complex for their understanding yet not so childish in content that the children's resentment produces a negative attitude. Because of the lack of such material, children of I.Q.'s between 70 and 90 are frequently found to be retarded in reading much below what one would expect from their mental age. Remedial procedures which have been successful in these classes have been not those where drill and formal, logically-arranged reading exercises have been employed, but those in which the pupils have first been helped to enlarge their background of experiences upon which a meaningful reading vocabulary can be built and to gain an interest in reading. Interest in reading was developed through interesting books which were made easily available and which were sufficiently within the reading level of each child so that he experienced a measure of success, often the first such experience in the field of reading. Interest was also aroused through having the child encounter situations in which he felt a real need for improving his reading ability.

Slow children, because they come into more frequent contact with normal and bright children than do the mentally retarded and because they are more sensitive than the latter, are much more insecure, as a group, than the mentally deficient. Moreover, though parents may recognize and accept the fact of mental deficiency in a child because of its greater obviousness and abnormality, they are usually prone to tell the slow child that he "could do it if he wanted to". In these instances, the school must help the parents to see that such an admonishment will only increase the child's feeling of inferiority with a consequent loss rather than gain in learning, with anti-social behavior as another unfortunate concomitant result of such prodging. SOCIAL AGE (DEVELOPMENTAL AGE). The stage of the maturity of a child's total personality. The stage of the child's social development is determined by scales or tests based largely on his play interests and his ability to handle himself in situations involving his care of himself and his behavior with others. While physical size and mental age are somewhat related to the social maturity of the child, a child may be mentally bright and still act like a baby; he may be small in stature and yet in his actions be independent and socially mature. Children make friends more frequently among other children of about the same social or developmental age, rather than of the same mental or chronological age. M.S.Q.

SOCIAL HYGIENE—See HYGIENE AND HEALTH EDUCATION.

SOCIAL INTELLIGENCE. Without social intelligence man cannot live effectively today. Without it he cannot distinguish those who exploit him — employer, congressman, salesman—from those who do not; he is unaware of alternatives to his way of living; he cannot remedy grievances because he doesn't know how to manipulate events to secure what he wants; he cannot make up his own mind reliably, yet he does not know when others make it up for him. He cannot, in short, make choices which serve his interests. Living without social intelligence is, moreover, quite incompatible with democracy, where each individual is expected to participate in management of the common social life and himself to enjoy as rich a life as possible.

What constitutes social intelligence? Though there will necessarily be differences in de-

gree from person to person, nevertheless certain elements can be differentiated. The first is knowledge of the world today: awareness of current happenings, but more—understanding of the problems and issues involved of their historical roots, and of the deeper movements of which the events are manifestations. Thus, in a significant dispute regarding wages for labor, the merely informed will know of the event, but the socially intelligent will know also that this single happening is imbedded in a cluster of problems and issues regarding distribution of wealth and will understand the deeper trends and movements (technological developments, trends to democracy) which constitute the real basis of the problem.

A second element is ability to form discriminated opinions. This involves ability to get information, to read, discuss, exchange ideas, and, in particular, ability and disposition to examine evidence, to see below the surface, to evaluate critically. With these skills one can utilize the ideas of others in forming his own opinions. Without them he is at the mercy of any who wish to mold his mind, to exploit him. Without them he cannot read a newspaper intelligently, possibly not even with safety. He will swallow what he hears; he will follow the party line. Facts, information, knowledge, of a sort, even the mentally enslaved citizens of a dictatorship have; discrimination, however, they do not display. The ability to form discriminated opinions seems one of the clearest evidences of democratic social intelligence.

But intelligence which is mere *knowing about* life today is insufficient. The citizen who merely observes and understands is impotent. A third necessary element, then, is ability to act, to shape the course of events. Certain events one can, if he is skilful, maneuver by himself. But for most outcomes in modern life group endeavor is necessary. Though one may individually recognize dishonest officials, it is only by cooperation with others that honorable ones can be elected instead. One must, then, know how to work with others, to enlist their interest and cooperation. He must know groups to approach or how to form them. He must be skilful in working with groups to find channels of action. Is such ability to effect essential to social intelligence? The answer will depend on

SOCIAL PLANNING — SOCIAL SERVICE ACTIVITIES

what we wish intelligence to eventuate in. It appears increasingly that a spectator type of social intelligence does not suffice.

SOCIAL SERVICE ACTIVITIES IN SCHOOLS. Social services in schools cover a wide range of activities set up in various ways and in varying degrees of completeness in different school systems, but all based on two generally accepted underlying principles. The first of these is the realization that a child is an organism which functions as a whole so that his mind cannot be separated and educated without reference to the other aspects of his total existence. The second principle is the conviction that each child is a unique individual differing in many ways from every other child, not only in physical development but also in mental ability, social experiences and attitudes.

As these two principles have forced themselves upon the attention of educators, and as other fields of knowledge—psychology, social case work, mental hygiene, and pediatrics—have developed, the schools have gradually assumed responsibility for adjusting their programs and routines, and for introducing new services to meet the needs of the total individual child. In doing this it has been found necessary to examine carefully each activity in order for the schools to avoid assuming functions and responsibilities which properly belong in other fields. For instance, the schools must assume responsibility for guarding the health of the children under their care, but they must avoid taking over the functions of community clinics or depart-

ments of public health. Also they must provide a case work service, through an attendance department or a visiting teacher department, or both, for handling individual problems of adjustment, but they must avoid administering relief as that service properly belongs in a department of public welfare. On the other hand, the services which are set up must be designed not only to work with individual children, but also to work cooperatively with such other agencies in the community as health agencies, recreational agencies, so that the services of those agencies can be brought to bear as effectively as possible upon the problems of maladjustment which appear in the schools. It is a further responsibility of all types of social services in schools to become aware of lacks in community resources as they appear through the unmet needs of individual children, and to help stimulate the proper agencies or institutions to develop the needed resources or services.

In some school systems, all types of social services are set up in one department or division under a single Assistant Superintendent or Director. In other systems, certain services are connected with one department and others with other departments. Some of the most usual types of social services found in most modern school systems today are the following:

The School Nurse. The school nurse is a graduate nurse who is further equipped with public health training. She functions not only as an assistant to the medical inspector in maintaining healthful living conditions in the school buildings and grounds, and in administering periodic health examinations to all school children, but also as a guide to individual children and parents by interpreting the importance of defects found through the health examinations and by aiding them in working out ways of having those defects corrected, either through their private physicians or through the use of community clinics. She understands the importance of working with individual children and parents in terms of their own family problems and understanding or acceptance of medical findings, rather than assuming that all parents react similarly.

School Attendance Workers. All states in the Union now have Compulsory Attend-

SOCIAL SERVICE ACTIVITIES IN SCHOOLS

ance Laws of some kind, but they vary greatly in the provisions of the laws and in enforcement machinery which has been set up by the different states. (See COMPULSORY ATTENDANCE.)

The trend is definitely away from the original concept of a "truant officer" whose function was simply to act as a police officer to patrol the streets and see that all children were in school, or at least off the streets during school hours. More and more school systems are recognizing irregular school attendance and truancy as evidence of social, educational, or emotional maladjustment. They are, therefore, seeing attendance work not primarily as a police function, but rather as a social service based on an ability to analyze the causes lying behind the symptoms of irregular attendance or truancy (*q.v.*) For this reason, some school systems have already set up educational standards for attendance workers and are insisting that these workers be trained in social case work so that they may deal with individual problems and be able to work cooperatively with other social agencies in the community on conditions causing truancy and later delinquency.

Visiting Teachers. "Visiting Teacher" was the original title used when the first school social workers were introduced into school systems in 1906-07. That title was changed by the national professional association in 1941 when the name of the association was officially changed from the *American Association of Visiting Teachers* to the *American Association of School Social Workers*.

The recognition of the need for this service grew out of the realization on the part of school people, settlement house workers, psychiatrists, and others in the community dealing with children's problems that many children were showing school maladjustments because of conditions lying outside the actual classroom situation.

As unfolding knowledge in the fields of mental hygiene, psychology, social work, and education itself began to throw more and more light on the sorts of difficulties which might cause problems in the smooth development of each child's personality and school progress, it became increasingly apparent that the classroom teacher and the school principal, alone, could not be expected to understand the causes of these problems, and to

develop the case work techniques necessary to work with individual parents and other community social agencies and institutions in eliminating them. The social worker, attached to the school system itself, with a knowledge of school conditions and techniques, but also equipped with case work skills, was seen as the technician who could best help school systems and community social agencies to coordinate their services for the benefit of individual children. In very many cases, the school social worker could help schools and homes to understand each other better and thereby enable them to work together to provide a more wholesome atmosphere for the child's developing personality and social and emotional adjustment.

There are as yet comparatively few visiting teachers, or school social workers, in the United States, but the need for them is gradually being accepted and their appointment in school systems is beginning to be looked upon by school administrators and laymen, not as added "frills," but rather as a necessary step in economizing energy and making education effective for as many children as possible.

Special Education for Exceptional Children. From the work of the school nurse, the trained attendance worker and the school social worker, as well as from the fields of pediatrics and individual psychology, there has come to the schools an appreciation of the need of certain groups of exceptional children for specialized education. We find in school systems now special classes for the slow learning child, the child with visual or hearing difficulties, the crippled child, and the child with speech difficulties, as well as teachers who visit the home of those children whose chronic illness precludes their attendance at school. Some school systems even recognize the exceptionally bright child as needing special class placement. (See EXCEPTIONAL CHILDREN, HANDICAPPED CHILDREN, SPECIAL CLASS.)

These special classes for exceptional children are mentioned under the heading of "Social Services" because the adjustment of the child and his parents to his placement in a special group, the interpretation to the parents and the children of the work in the special class, and the vocational and personal guidance connected with the work of these

SOCIAL STUDIES IN THE SCHOOLS, COMMISSION ON

classes all require the services of someone trained in case work techniques, if the classes are to function successfully. In many school systems which maintain a special class program, visiting teachers are attached to the department of special education for this purpose.

Other Social Services In Schools.

Various other sorts of social services are found in various forms in some school systems. Free lunches for indigent or undernourished children are now provided in many school systems through the participation of the federal government and the use of excess commodities. Parent teacher associations in some schools provide funds for clothes and shoes for needy children in the school population. In some communities, High School Scholarship Associations have been set up to provide carfare and lunch money for children showing ability to continue their education but lacking money for these minimum essentials. These are usually financed by private contributions.

SOCIAL STUDIES IN THE SCHOOLS, COMMISSION ON THE (American Historical Association). The Commission on the Social Studies in the Schools was organized as the result of a growing awareness of the fundamental problems created by the rapid industrialization of American society. The general public, social scientists, and educators, recognized the existing discrepancies between the prevailing conception of policy and program in the social studies and the educational needs of a dynamic, expanding society. In 1925 the American Historical Association accepted a request

the resources of social science and educational research upon the problem of educating youth for participation in, and direction of, a new age. The Commonwealth Fund provided money for planning, and a directing board was organized which included economists, sociologists, geographers, educational research workers and educational administrators, as well as historians. Beginning in January, 1929, the Commission carried out a five-year program of investigation financed by grants of the Carnegie Foundation totalling \$340,000.

While purely technical and professional study of the teaching of the social sciences was a part of the inquiry, the Commission took a broad conception of its work and directed its attention to considerations of national history and policy and its world setting, interrelationships of school and society, conflicts and pressures in economic and social life; and to the "meanings, purposes, and potentialities" of American democracy, in order to orient educational philosophy and purpose. The Commission secured the service of technical experts to study and report upon detailed aspects of the investigation.

The findings of the Commission were summarized in *Conclusions and Recommendations of the Commission*, which appeared in 1934. The majority of its members believed that individualism, with its concomitants of capitalism and class distinction, is engaged in a struggle with a social and collectivistic society of planned economy and mass rights. Although the present era is primarily one of adjustment and transition, current trends indicated that the latter social organization would dominate the future. Thus a broad plan was needed which would enable education to meet the demands of an emerging collectivism, while securing the individual from bureaucratic tyranny.

To implement this frame of reference the Commission proposed that "the attitudes and outlook of the American people, especially the rising generation, be 'profoundly' altered to frank recognition of the new order, but through education in democratic ideals and practice, not through coercion or regimentation. In selecting and organizing curricular materials, continuation in school through adolescence with opportunity for

SOCIAL STUDIES, TEACHING OF

despite economic insecurity. Equal opportunity for the development of creativity, spirituality, and individuality was to be fostered by participation in social projects in the elementary schools, and by emphasis in the secondary schools upon broad courses in the social studies with more attention given to literature and to the methods and instruments of scientific inquiry.

The Commission placed its faith in "the competence and spiritual power of the individual teacher", but recognized the necessity for improved conditions and rewards of work, and a new direction in teacher training. Teachers must be freed from the rigid, detailed supervision which prevented freedom in teaching realistic and independent understanding of social pressures and issues. Thorough grounding in socially useful knowledge rather than the mastery of techniques and formulæ characterized the education of teachers. In the education of administrators, emphasis was placed upon "social sciences, social philosophy, and statecraft". Finally, the Commission recommended that teachers aspire to positions of leadership and influence, and that educators become more effectively organized so that education might defend itself against the attacks of "selfish minorities and ignorant majorities".

The *Conclusions and Recommendations* aroused a great deal of controversy principally because of their collectivistic emphasis, active partisanship, and failure to provide specific materials and methods. Four of the Commission's sixteen members refused to sign the report. It is too early to assess the final significance of the frame of reference presented by the Commission on the Social Studies in the Schools. However, the broad scope of their investigations provides a new perspective on American education. The sixteen technical studies, most of which appeared after the publication of the *Conclusions and Recommendations*, answer the demand for greater detail and deal with hitherto neglected aspects of the interplay of educational and other social forces. (See SOCIAL STUDIES, TEACHING OF.) K.R.H.

SOCIAL STUDIES, TEACHING OF.

Definition. A clear understanding of the place of the social studies in the instructional program of the schools necessitates a grasp of the significant differences between the *social sciences* and the *social studies*. The social sciences are organized bodies of knowledge built up from the formal, scholarly, and advanced studies which deal with various aspects of human cooperation and conflict. They constitute the systematized record and thought about human experience and knowledge concerning man's interrelationships. They promote the broad social purpose of providing a perspective within which human relationships may be described, classified, and explained so that man may bring this knowledge to bear on the solution of present problems.

The social sciences include several major fields. 1. *Cultural anthropology* is the study of the customs, folklore, social activities, and organizations resulting from man's reaction to his environment, especially in the origins of social behavior. 2. *Economics* deals with the material aspects of satisfying human desires. This may be an historical approach or a quantitative study of current practices. 3. *Geography* (*q.v.*) may be both a natural science (physical geography) and a social science (human geography). The concern of the latter study is to describe and explain man's environment, both natural and cultural. 4. *History* is the oldest of the social sciences and is the parent trunk from which all the others have stemmed. In its restricted scope it is the study of man's experience organized in chronological sequence. 5. *Political science* covers the field of organized control of human society by means of government. It is concerned with all forms of such control as developed in the past, but main emphasis has been devoted to the forms and functions of the national states and their subdivisions. 6. *Social psychology* is the study of the impact and the resultant reactions of events and in-

stitutions upon the human mind. 7. *Sociology* is the study of the forms, institutions, and functions of human groups.

The social studies consist of portions of the social sciences selected, simplified, and adapted for the purpose of instruction in the schools. The difference between the two is in their purpose and degree of difficulty rather than in the nature of their content. Both deal with human relationships, but the social studies are simplified and presented so as to provide introductory stages of increasing complexity on the road to the social sciences. Both have social utility as their ultimate purpose, but the immediate concern of the social studies is instructional utility. The frame of reference conditioning all instruction in the social studies, as proposed by Beard (*A Charter for the Social Sciences*, Scribners, 1932, p. 2), consists of the spirit and letter of scholarship, the social realities of our times, and the nature of the teaching and learning process in the various grade levels across which it is distributed. A monograph on "A New Interpretation of the Articles of Confederation" would belong in the field of the social sciences, but presented as "A Unit on How the American Colonies Devised Their Own Form of Government" it would belong rather in the social studies since by its title it is obviously designed for instructional purposes. Completely different terms would make the distinction self-evident, as is the case with "political science" and "civics." One may belabor the distinction too much, but a practical distinction can and should be made for the purpose of clarifying and facilitating educational discussion.

There is no definite distinction between the social studies offered in the elementary school and those offered in the secondary school. The elementary programs are much more simplified, are more integrated with other studies on the same grade level, and have the understanding of more immediate and specific human relations as their primary object. They usually begin with a consideration of the home, the family, the school, and the community and develop into a more systematized study of geography, local and national history, and civics in the intermediate grades. The secondary school covers these fields in greater depth and detail and adds more specialized treatment of sociology, economics,

and government. According to Wesley (*Teaching the Social Studies*, p. 50), the most frequent offering in the social studies in the upper four years of the secondary school are: Grade IX: world history, commercial geography, civics; Grade X: history of world civilization; Grade XI: American history, state history, government, economics, problems; Grade XII: problems, sociology, economics, government.

Status of the social studies in the schools. Three major elements are combined to form the social studies, namely information, skills, and social practices. Information about human relationships may be drawn from books, newspapers, pamphlets, pictures, models, specimens, maps, charts, etc. This information is for the most part outside the orbit of immediate experience of the pupils and provides data in organized form about human relationships which are considered essential to an understanding of the form and functioning of society. It may vary from a study of the customs of the ancient Egyptians to a consideration of the pattern of dictatorship in the modern world.

The second major element consists of certain skills and processes. The memorization of many details of factual information may be a sterile accomplishment in terms of promoting the ability to think critically and constructively about human relationships. Since part of the ultimate purpose of the instruction is to develop individuals who can assume a responsible place in society, they must be afforded some practice in attacking social problems under expert direction. To attain this particular end, emphasis is placed upon developing ability to discover and analyze a problem, gather and evaluate the data necessary to propose a solution, and if possible to test that solution. Past problems of society afford excellent material for pupils to practice upon. These frequently have the advantage of having had some ultimate solution worked out so that the pupils may compare their own with society's solution, and also of being sufficiently removed in time and space so that they may be considered objectively and not be obscured by the heat of current controversy. A healthy critical attitude and less possibility of overconfidence will result if pupils are also occasionally directed into a study of current problems for

which no practicable solution has yet been found and which they will have to face as coming citizens.

The third major element consists of a number of peripheral aspects which combine actual pupil experience with guided learning about human relationships. These areas, which may be studied formally or incidentally, largely comprise elements recently added to the life of the school. Since they do deal with social relationships and have a very definite social purpose, they are more logically, though not always necessarily, considered as a part of the social studies offering. Examples are programs dealing with vocational guidance, community survey or service, regional geography, school citizenship, extra-curricular activities, sex information, and social behavior.

Values claimed for the social studies as school subjects have naturally reflected changing social philosophy. Traditional aims stressed moral and ethical values; more recent emphases have been on developing knowledge, understandings, skills, attitudes, and interests which will equip young people to take their proper rôle in a democratic and interdependent society. Recognition of the desirability of this preparation is evidenced by the fact that in time allotment the social studies now occupy a place second only to English as a school offering.

Problems in adapting materials for instruction. Before the social sciences can be transformed into the social studies, they must be adapted to meet the requirements of the organization of the school. Although this process of adaptation is not carried on in separate and distinct steps, a clearer understanding of the principles involved will be possible if the three major problems of selection, organization, and grading of materials are considered separately.

Selection: The existence of a practically unlimited amount of material makes the adoption of some principle of selection necessary. Many specific principles have been proposed which tend to cluster around three major ideas. 1. The needs and activities of good citizens may be determined by a survey of social practice. Objections to this are that it is a cumbersome method and one which also rests finally on current opinion. 2. A program may be built up around pupil needs and in-

terests. This point of view, although limited in too naive an application, has contributed to more vitalized instruction and has shifted emphasis away from undue attention to subject content. 3. Prevailing educational practice or frequency of mention in publications may provide a useful guide in the selection of materials. This principle, however, is open to the criticism that it assumes current practice is satisfactory; it may also result in setting up a program of study too inflexible in relation to changing conditions and the local environment.

Organization: Materials must be organized to meet the difficult requirements of provision for individual differences, and adjustments necessary to horizontal and vertical integration. Variations in organization have ranged all the way from straight subject matter to complete integration or fusion (*q.q.v.*), where the identity of the individual subjects is completely submerged. Prevailing practice favors a modified subject matter approach as more advantageous for the purpose of learning, with many of the benefits of integration obtained through correlations among units, problems, and projects. This type of approach has evolved towards a unity of concept not possible when completely separate subjects were offered.

Grading: Determining the most appropriate grade level on which to offer materials is not easy because the social studies seem to have no clearly discernible order of difficulty. In addition, pupils bring many preconceived ideas to the classroom and the influences of a bewildering mass of outside agencies such as newspapers, radio, and motion pictures prevent the teacher from controlling more than a fraction of the social learning of his pupils. Abstract and generalized materials are gradually added as the child advances up the educational ladder. Krey has classified the steps of sequential social learning as follows (Kelley, T. R., and Krey, A. C. *Tests and Measurements in the Social Sciences*, Scribners, 1934, p. 13): (1) places, concrete objects, and persons; (2) events; (3) simple relationships of time and place; (4) relationships to material world; (5) relationships among people; (6) concepts denoting intricate social relationships. The lack of any universally applicable principle of grading has resulted in

great diversity in practice. (See GRADE PLACEMENT, CURRICULUM.)

The selection, organization, and grading of materials for social studies instruction will doubtless lead to continual adaptation and diversification, because the changing standards of what is considered important by society will require constant adaptation of the curriculum.

Trends in Social Studies Teaching. Various aspects of the social studies program are interwoven into a pattern involving content and curricular organization as well as methods, so that these may be considered together under the following headings:

1. *Deformalizing of teaching and more vital motivation of pupils' work:* In common with other subjects, teaching in the social studies has adapted its methodology to consider the child's learning rather than the subject content as a focal point. This has directed emphasis to the elements of the pupils' own social experience which may be advantageously drawn upon to furnish part of the instructional program. The modern teacher uses a flexible classroom approach and motivates a cultivated interest in the regular content material through the channels of the natural interests and activities of children.

2. *Enrichment of methods by use of many aids to instruction:* The availability of many supplementary materials has permitted teachers to break away from the single text book. School libraries contain many books for reference and collateral reading for all levels of ability. Most communities large enough to support a high school have a newspaper of some kind; many classrooms and practically all homes have radio sets; pupils of all ages who are within accessible distance attend the motion pictures. Much of the material from these sources is concerned with human relationships and may therefore be used directly. There are in addition many other readily available instructional aids in the form of maps, charts, graphs, specimens, models, government bulletins, pictures, etc. (See AUDIO-VISUAL AIDS, MOTION PICTURES IN EDUCATION, RADIO IN EDUCATION.)

3. *Use of activities to provide experiential learning:* In his widely quoted precept "We learn by doing," John Dewey (*q.v.*) voiced not only a psychological truth but also a criticism of much that was traditional in

classroom procedure. The introduction of activities related to socially significant learning has done much to improve instructional methods. Activities in the social studies range from the concrete ones in the elementary school, such as construction of a straw hut for "tribal meetings," to the more intellectual type in the secondary school, such as visiting the city council or the local bank to observe the practical operation of principles previously studied and discussed. Activities must be expertly guided to insure the realization of significant learning outcomes and the avoidance of waste of time and effort.

4. *Emphasis on the more permanent elements of learning:* Major attention in the traditional social studies program has been on having pupils learn a large volume of factual information on the assumption that other outcomes would automatically be realized. Numerous follow-up studies revealed the disturbing certainty that other objectives frequently were not attained and also that the great majority of the separate facts were forgotten within a relatively short time. Methods are therefore being modified to take into account more permanent outcomes such as critical analysis of a problem, locating and evaluating sources of information, drawing inferences, and making generalizations. These are not taught separately but are developed through directed study and classroom discussion as a part of the total process of social learning, and involve actual practice as a guarantee of more permanent retention. The National Council for the Social Studies has devoted an entire Yearbook to "critical thinking." (See CRITICAL ATTITUDE.) Development of skills and relevant thought processes has been aided by the development of diagnostic tests designed to detect the deficiencies of pupils and to stimulate them towards improvement. (For examples see item under Morse and McCune in bibliography below.)

5. *Introduction of new topics:* The range of offering has been broadened by the addition of new content materials and greater variations in courses. Some addition comes from an increase in the availability of reference materials, outside aids to instruction, community contacts, etc. A large part comes from public interest in new or neglected topics. War, for instance, stimulates interest

SOCIAL STUDIES, TEACHING OF

in a number of new subjects. Some of these are the Far East, Latin America, airplane transportation, global geography, civilian economy, world organizations—past and present, organization and function of the branches of military service, and problems of post-war planning and reconstruction. Widespread public interest has also resulted in the introduction of courses in consumer education (*q.v.*) in many schools. Arguments for the inclusion of this topic in social studies' curricula are that it would improve management of individual affairs, would provide an understanding and therefore a better functioning of free private enterprise, and would provide the basis for a more intelligent application of social planning and management.

6. *Increased attention to contemporary aspects:* A frequently justified complaint against the traditional social studies program was that it lacked reality in being completely divorced from the contemporary scene. Some adjustment has been made in providing actual courses centered around community and national problems, where emphasis is on the present, and in adopting "current events" as a supplement to the social studies program throughout all grade levels. There is no complete agreement as to how current events may best be used. Viewpoints vary all the way from proposing a purely incidental correlation with the regular subject matter of the course to a systematic study based on assigned reading in papers and periodicals. The teacher using current events extensively should endeavor to select them with care so that the socially significant aspects are stressed rather than the trivial and sensational, and relate them wherever possible to the regular course content so that the whole will combine to provide a fuller understanding of the contemporary world. Too much stress on current events unsupported by some historical perspective may yield only a shallow and distorted impression of the present.

7. *Community study and regional consciousness:* Emphasis on contemporary aspects of society has directed attention also to using the community as a laboratory for the social studies. Field trips, school journeys, and local surveys have been utilized to provide pupils with direct experience. There are innumerable comparisons, contrasts, and illustrations of social phenomena within the

local scene which the alert and informed teacher can draw upon to make the study of abstract principles or remote times meaningful. But, as for example in using current news, one must be careful to select the socially significant elements for emphasis. Howard Wilson points out a prevalent misuse of this approach (*N.C.S.S. Fourteenth Yearbook, Critical Thinking*, 1942, p. 120): "As one reads through the rapidly growing literature on the use of school and community in civic education, he is impressed with the fact that we have commonly been intent simply on using school and community as a new body of subject matter, and have focussed attention on the acquisition of information rather than on the process of thinking and acting in that area as much as we have in the areas with which school books deal."

The customary stress on political boundaries has also obscured the fact that more significant geographical features often bind states and parts of states into economic, commercial, and cultural regions. Some social studies programs have been evolved which utilize these regional characteristics and resources. Gearing the instructional program to the region provides a unified, logical approach; draws on the direct experiences of the pupils; and provides a consciousness of regional problems as a basis for subsequent participation as adults. (For example of a social studies program of this type, see item in bibliography below under Krey.)

8. *Awareness of the personal aspects of method:* The availability of many instructional aids and the increasing flexibility possible in the schools of today have freed the teacher from the necessity of following rigidly any one method, such as question-and-answer, or the steps of the various unit-mastery techniques. The personality, experience, and training of the teacher are so much a part of any approach he may use that a method successfully used by one teacher may be sterile or ineffective if copied by another. The best methods for a teacher to use are those which he finds on the basis of experience are most effective in promoting meaningful learning in an atmosphere of mutual respect and harmonious relationship.

9. *Wide experimentation with local courses of study:* Dissatisfaction with the traditional program has brought about a break from

ready-made programs and courses of study. Increasing emphasis on community and regional aspects and awareness of the importance of contemporary developments have combined to launch wide experimentation which has led to great diversity, sometimes mistaken for disorderly confusion by those who do not understand the reasons behind it. As long as this experimentation is undertaken intelligently and with real purpose, the resultant diversity may be regarded as a sign of vigor and growth.

10. *Acceptance of idea of social planning:* The rapid exhaustion of our natural resources plus the spectacle of privation in a land of plenty have turned the attention of thoughtful leaders in all fields to a consideration of greater economy of natural and human resources through intelligent planning. Some management of the national economy in the interests of a majority of the people is not incompatible with individual freedom nor free enterprise. Careful programs for conservation of soil, reforestation, etc., have already won wide popular approval and support. Social insurance is a promising beginning towards a condition of freedom from want for all the people. It is particularly within the realm of the social scientist to diagnose social ills and foresee social trends. A well managed program for teaching the significance and benefits of social planning can be instrumental in securing wide acceptance of the concept, and can therefore be one of the most important elements of instruction in the social studies. SOCIAL WORK IN SCHOOLS — See SOCIAL SERVICE ACTIVITIES IN SCHOOLS.

SOCIALIZED PROCEDURE. The *socialized recitation* is one in which classroom activities are viewed as cooperative enterprises, with pupils and teacher working together to achieve ends that are acceptable to all its members.

The socialized recitation is an outgrowth of Dewey's philosophy with its emphasis on education as primarily a social process which should take place in social situations approximating life situations. To be sure, the socialized recitation should help pupils to acquire desired subject matter abilities, understandings, and facts, but it should also help the pupils to develop the abilities and attitudes that are important in making personal adjustments in social situations. The socialized procedure includes experiences that foster favorable attitudes toward cooperation, respect for the rights of others, dependability, and other desirable personal and social traits. Through participation in group activities, pupils learn how to work with others, both as leaders and as members of the group. Socialized procedures, if wisely guided and supervised, give the child a better understanding of the nature and importance of group relationships and individual responsibilities than can be attained in any other way.

Though the spirit and the purpose of the socialized procedure may be expressed in many forms, there are two major types. In the first, the formal type, the class is organized in imitation of some adult group or social institution, such as a club, a court, or a city council. After effecting the organization, pupils carry out the work of such an organization in order to understand its functions. Thus the members of a class organized as a court to try students who have violated school regulations gain insight into the ways our courts safeguard the rights of both the individual and society.

SOCIALIZED PROCEDURE

The second type of socialized procedure is much more informal, stressing the spirit of socialized procedure rather than its form. What distinguishes this informal type of socialized procedure from traditional classroom practices is that the socialized procedures stress the importance of social needs and not the teacher's demands as determining the nature of pupil activities. In both the traditional classroom and the socialized classroom a student may read to the group the letter he has written, and the other students will criticize that letter. In the traditional classroom, both the child who reads the letter and the students who make the comments are interested primarily in the way the teacher will grade their efforts. In the socialized recitation, however, both the reading and the criticism arise from social rather than teacher-imposed reasons. The child reads his letter because he wants to improve it by getting his classmates' reactions, and his classmates criticize the letter because they want to help him improve it. What grades the teacher will assign, or even whether the teacher will grade their efforts at all, is of minor importance.

Where the meaning of the socialized recitation is not understood fully, teachers tend to imitate the organization of a socialized recitation rather than to exemplify its spirit. Even though the students' seats are arranged in a circle rather than in rows, with the teacher seated as one of the group rather than standing at the front of the room, the ensuing discussion may nevertheless be dominated so completely by the teacher that the change in the plan of seating becomes meaningless. A student chairman leading the discussion according to a detailed plan prepared in advance by the teacher represents only a change in the person who asks the questions rather than a fundamental shift in the center of attention from the teacher to the students. Any type of pupil activity may be used in a socialized recitation if it contributes effectively to the attainment of the desired outcomes. The purpose is to secure wholehearted, purposeful, worthwhile participation on the part of the pupils. In practice these activities may vary from the rather limited recitation-discussion type under teacher leadership to situations in which the pupils are given the responsibility for planning and conducting all the activities of the period.

The values of socialized procedures depend much upon the teacher's insight and tact in guiding the selection, organization, and direction of activities. Desirable as pupil participation is, there is little value in purposeless and uncontrolled pupil activities. In planning such work the teacher should keep in mind some of the more important limitations of the socialized procedure. (1) Some objectives of education can be attained more effectively through direct teaching than through socialized activities, for instance, the acquisition of such skills as the use of fundamental arithmetic operations or the correct use of the preterit in a foreign language. On the other hand, a discussion of the various interpretations of a poem the students have read is well-adapted to a socialized procedure. (2) The socialization of activities cannot go beyond the pupils' willingness and ability to carry on the activities. Sustained group interest is essential to a successful socialized activity. If this is not present, perhaps because of difficulties beyond the pupil's depth or of subject matter that seems meaningless to the students, the activity may bog down into a meaningless, tiresome chore. (3) The real objectives may be lost sight of if the pupils become absorbed in the activities for the sake of the activities. As indicated above, some devices may become mere matters of form instead of vital learning activities. (4) If some pupils are not inclined to accept the class activities seriously, discipline problems are likely to arise. The high schools now have many older students who attend school because of the upward extension of the compulsory school age and not because they know they are profiting from their experiences at school. Such students as these, who regard classwork only as an unnecessary obstacle to their being free to go to work, may demoralize the entire group and use the apparent freedom of the socialized procedure as an invitation to horseplay. SOCIALIZED RECITATION—See **SOCIALIZED PROCEDURE**.

SOCIETY OF FELLOWS, HARVARD UNIVERSITY. The Society of Fellows, founded in 1933 by President Emeritus A. Lawrence Lowell, seeks to furnish the means to a number of carefully chosen graduate students of attaining a high standard of intellectual achievement free from pressure of routine tests and demands for immediate achievement, as well as from strain imposed by financial considerations. Candidates for Junior Fellowships are interviewed each year at Harvard by the Senior Fellows—the managing body of the Society, consisting of the President of the University and the Dean of the Faculty of Arts and Sciences, *ex-officio*, a Chairman, and at present five other men appointed by the Corporation. Since the total number of Junior Fellows may not exceed twenty-four, approximately eight are selected each year from among the candidates.

The Junior Fellows are elected for a term of three years, with the possibility at the end of the first term of re-election for an additional three years. During the first term they receive a yearly stipend of \$1,250 and during the second, of \$1,500, together with room and meals in one of the Harvard Houses. Married Junior Fellows receive \$750 in commutation for room and board. Junior Fellows have all the privileges of any instruction given in the University, but receive no credit for courses and are not candidates for any degree. The facilities of the University are at their disposal and they are permitted to pursue their chosen fields of educational activity, the attendant expenses being paid by the Society. At the end of a first-term appointment a Junior Fellow who still gives a strong indication of scholastic promises of a fundamental nature may, on the recommendation of the Senior Fellows, be reappointed by the Corporation for a second term not exceeding three years. Such a reappointment is not treated as normal.

During his membership in the Society the Junior Fellow meets formally and informally with the Senior Fellows, with other Junior Fellows, and with guests, young and old, who represent various areas of thought and action. By this means President Lowell hoped to transcend the limitations imposed by the doc-

torate by enabling the Junior Fellow to look beyond his own specialty and to see something of the range of knowledge as a whole and something of the seriousness and value of disciplines remote from his own. A.D.N.

SOCRATIC METHOD. The aim of the Socratic method was to bring the pupil to the point where he would be able to realize his ignorance and thus acquire the attitude of the true learner. As developed by Socrates, this conversation or quiz method, sometimes called the “dialectic” method, has two stages: (1) the “ironic” or destructive phase in which, by skillful questioning, the pupil is brought from unconscious ignorance to conscious ignorance; (2) the “maieutic” or constructive phase in which, by further questioning, the pupil is led from conscious ignorance to clear and rational truth. Socrates called the teacher the “gadfly of thought” and the “intellectual midwife,” claiming that the teacher’s function is merely to create in the pupil the spirit of the learner and to stimulate his mental activity by suggestions and guidance.

Although the Socratic method is used in modern education, there is always the grave danger that it is easier for the teacher to employ the ironic part of the Socratic quiz than the constructive phase. Indeed many teachers lack the ability to use a series of questions as a method of developing an understanding of a major concept, especially under classroom conditions. There is also the danger that the teacher, in his zeal to break down unconscious ignorance, may employ sarcasm to an unwholesome extent. The Socratic method can be very effective in overcoming common misconceptions and prejudices, provided that it leads, as Socrates would have it, to the consciousness of truth and not merely to the consciousness of ignorance. SPEARMAN - BROWN PROPHECY FORMULA. The Spearman-Brown formula is used in order to determine the equation which, given the reliability coefficient of a test of unit length, yields an estimate of the reliability of the same test when made A times as long, where A may be greater or less than 1. The equation reads

$$r_{AA} = \frac{Ar_{II}}{1 + (A-1)r_{II}},$$

in which r_{II} is the reliability coefficient of a test of unitary length and r_{AA} is the estimated reliability of a test A times as long. The general principle is that the longer a test of the same kind of material, the more reliable it is, but not in linear relation with length, for a law of diminishing returns is involved. The point should be stressed that lengthening a test will increase reliability in line with this equation only if the added material is genuinely homogeneous with that already in the test. The equation is found empirically to hold not only for test scores but also for increasing the number of judgments as in the use of rating scales and even in connection with increasing the number of categories of judgment, up to 5 or 7. The equation can be used in reverse, or, solving for A , we can estimate how much the length of a test should be changed in order to attain some specified reliability coefficient. (See RELIABILITY.) SPECIAL ABILITIES. The concept of special abilities implies an unevenness of ability somewhat in contradiction to the theory of general intelligence. As a matter of fact, little truth has been found either in the belief that "all good things go together" or in the converse that "nature" provides those who are defective in one direction with a special compensatory talent. Correlations of "good" traits have always been found to be positive, but in many cases very low or close to zero. Tests of physically handicapped children—the deaf, the blind, the mute, and

the crippled—have not shown them to be superior in some sensory ability which they did possess, and their average intelligence has proved to be somewhat lower than that of the physically normal children. Nor have mentally deficient children been found to excel in manual or artistic ability. The present consensus of expert opinion is that special talents are not found unless there is at least normal intelligence, but that superior intelligence is not necessary for special talents to occur.

Psychologists and educators are widely ready to believe that individual differences in most specific abilities are due to the factor of general intelligence plus the effect of varying environment, interest and training, plus variation in physical factors needed for that ability. However, in the creative and expressive fields, there is the tendency to retain the belief in specific inborn talent. Unfortunately, tests of aptitude in music and art measure mostly sensory capacity rather than creative talent, and outstanding sensory capacity is not always linked with creative talent. Inasmuch as good sensory capacity is necessary for good musical performance, tests like the *Seashore Musical Talent Tests* will successfully identify those who will attain only inferior results even with much training, but will have little success in the identification of those who with training eventually become outstanding musicians. As for graphic talent, though Goodenough found that in the early years a test of drawing ability can serve as a rather good test of general intelligence, in the later years no such relationship is found. On the other hand, individual cases have been found of high-grade mental defectives who, having a sort of photographic memory plus good manual dexterity, have been able to reproduce on paper anything they have seen with exact proportion and perspective and excellent detail. Nevertheless, such children have never become artists since the mentally-retarded lack the imagination and the emotional sensitivity which the artist in any field needs in addition to good craftsmanship. This common factor of imagination and sensitivity plus the evidence that quite a number of artists have worked successfully in more than one medium, has led some persons to believe in a special inborn trait of general creative ability and artistic inclination. Since

SPECIAL CLASS

educators have not yet devised techniques which clearly influence creative ability, it is difficult to disprove the hypothesis of "natural" creative talent except as one can point to eras in the history of a nation when talent in a certain field was relatively so prevalent that inherited capacity can be doubted to have been the one significant factor which produced the phenomenon. It is hopeful that Jersild, summing up the research in the development of musical ability, concludes that though there are large individual differences in musical ability as in other things, a systematic program of music education can be set up in music as in other fields of learning. (See *Child Development and the Curriculum*, Thirty-Eighth Yearbook of the N.S.S.E., 1939, Chap. VI.) Progressive schools have sought to answer the problem of how to select and train those with special talents by providing all students with wide opportunity and encouragement for artistic expression in the belief that this will at least develop æsthetic appreciation in all, even if genuine creative ability is not so easily trained. B.B.F.

SPECIAL CLASS. Pupils with mental and physical deficiencies are sometimes segregated in special classes within the same public school which educates normal children. When the special class is one including only one type of deficiency, instruction and care can be adapted to the needs of the children. The most common special class is that for children with retarded mental development, defined as below 70 or 75 I.Q. While the deaf and blind are usually educated in special schools, lip-reading classes are sometimes provided for the hard of hearing who attend the regular schools. There are also a number of sight-conservation classes for the partially blind, where a good deal of the instruction is oral and specially printed materials are used. The segregation of the cardiacs is less approved than the segregation of the mentally retarded or the partially blind. It is felt that segregation should be made only in those cases where the special deficiency prevents the child from benefiting from the instruction given in the normal class or where sufficient adaptation to the special health needs of the physically handicapped child cannot be made in the regular class. It is argued that defective children will have to learn to live with normal people and in a normal environment

and that, if possible, they must be trained to adapt themselves to such living. Even when it is best to provide special classes for children with a certain type of deficiency, the school organization should be such that the deficient children mix with the others in some classes and at some events.

Most special classes for the mentally retarded are in the elementary school but some are now provided in junior high schools where students can use the same shops and often be in the same shop classes as the other children, although their instruction in reading, writing, arithmetic, history, etc., is provided for in a special class. The special classes for the mentally retarded have proved their worth in that mentally defective children in special classes attain higher educational achievement than those kept in regular classes. The number of special class children who show serious maladjustments or become juvenile delinquents is fewer than those of similar I.Q.'s in regular classes. Prevocational and vocational training form a large part of the program for both the mentally and the physically handicapped of adolescent age.

At present, special classes are providing for only a small percentage of defective children who are not in special schools or institutions. The extra cost of the program, owing mostly to the small size of the classes, keeps many school systems from arranging for special education. Teachers of special classes occasionally get higher salaries and have training in addition to that of other elementary or junior high school teachers. To encourage special classes, some states provide more state aid for handicapped students educated in special classes than for students educated in normal classes. The State Education Law may designate certain types of special classes as either permissive or mandatory under certain conditions. A number of states include gifted children among those for whom special education must be planned. Special classes for the very bright are found in a number of schools. At present there seem to be about as many schools which are eliminating their special classes for the bright as there are schools which are just beginning to form them. (See **EXCEPTIONAL CHILD; HANDICAPPED CHILDREN; MENTAL DEFICIENCY.**) B.B.F.

SPECIAL DISABILITY. It is found occasionally that children with average or above average intelligence exhibit some special disability which prevents most methods of instruction from being effective. Color blindness is a special disability possessed by some persons who otherwise have excellent vision. "Word blindness" is a defect attributed to those of normal intelligence who have not been able to distinguish one word from another in spite of much perseverance. Since it is reported that many "word-blind" persons have learned to read by tracing the outline of the letters with their finger and later reading without the finger-tracing, it is difficult to tell just what this "word-blindness" consists of. At one time it was thought that a large number of persons were tone-deaf. Music teachers, however, now tend to claim that there are practically no persons so completely tone-deaf that they cannot learn to recognize different tunes. There have been cases of individuals over thirty years of age who up to that time had never been able to identify any melody, not even the national anthem, but who eventually did learn not only to recognize tunes but to sing songs. Speech defects such as stammering, stuttering, lisping, can also be listed as special disabilities. Where a particular learning depends upon a particular physical organ, deficiency in that organ may cause a special learning disability. When the physical disability cannot itself be measured, it is not always possible to tell whether the learning disability is due to an impoverished environment, to a teaching method not suited to that individual, to some personality maladjustment, or to an actual disability which cannot be overcome. (See **READING DISABILITY; REMEDIAL INSTRUCTION.**)

B.B.F.

SPECIAL SUPERVISOR—See **SUPERVISION OF INSTRUCTION.**

SPECIAL TEACHER. This term applies to the instructor who teaches a particular subject throughout a school or schools (i.e., special teacher of music, penmanship, art, etc.), as contrasted with the regular teacher who spends all of his time with a particular grade or class. The term is used also to refer to a helping teacher who assists the regular

teacher with atypical children. The objective in a situation of this kind is the individualization of pupil progress for both the typical and atypical.

The practice of having special teachers of particular subjects has been criticized as being contrary to the present emphasis on the child's integrated development. The elementary school child should be regarded, say these critics, as a rounded personality and not as the possessor of a series of discrete abilities, each to be cultivated by a specialist. Those who object to the employment of special teachers on this ground prefer to have the special subjects taught by the regular teacher, whose emphasis is on the total child rather than on the development of separate skills.

On the other hand, those who favor the appointment of special teachers of particular subjects point to the fact that no one teacher can be expert in all the specialized fields of speech education, art, music, health education, etc. To insist on having these subjects taught by the regular teacher is to invite mediocre teaching rather than the expert guidance of a specialist.

Many schools attempt to reconcile these opposing points of view by designating the special teachers as consultants who work with, but do not replace, the regular teacher. For example, when the students are at work on a project the art teacher is brought in to advise on the art phases, and the music teacher assists with the music. In this way, the students benefit from the special contributions of experts in the various fields, while the regular teacher continues to assume the responsibility of safeguarding the essential unity of purpose of all classroom activities.

SPECIALIZED HIGH SCHOOL—See **COMPREHENSIVE HIGH SCHOOL.**

SPEECH CORRECTION. The correction of speech disorders in the United States is largely in the hands of educators. However, according to the White House Conference report of 1931, surprisingly few educational systems provide special teachers of speech correction. The report estimates that approximately 60,000 speech handicapped children receive re-education at the hands of teachers trained in speech improvement or

SPEECH CORRECTION

correction. This number indicates that only a beginning has been made in caring for the speech needs of an estimated two million children with speech handicaps in the schools of the United States. Since 1931, speech correction programs have become more widespread. Evidence of this is the recent establishment of state programs of speech correction in Missouri, Louisiana, Florida, and Indiana. Prior to 1931 only two states, Wisconsin and California, provided aid to communities willing to defray part of the salaries of speech correctionists.

Speech correction programs maintained by large city school systems (e.g., Detroit, New York, and San Francisco) have been in existence for a relatively long period of time. Corps of specialists in these systems ordinarily administer speech correction weekly to children in the elementary and secondary schools, and are assigned a number of schools for visitation and supervision.

Another source of speech correction is the clinics maintained by colleges, universities, and—to a lesser extent—hospitals and medical schools. Such clinics are listed by the American Speech Correction Association, which maintains a Bureau of Information at Queens College, Flushing, New York. The speech clinics maintained by colleges and universities serve not only their own speech-handicapped students but frequently the children and adults of their community as well. A few have instituted traveling speech clinics to serve outlying districts.

Speech Defectives. Children and adults suffering from speech and hearing handicaps are indeed numerous. A consideration of a few of the more common kinds of handicaps of this type, together with their estimated distribution, indicates that every community has a significant problem of speech and hearing re-education.

Cleft palate speech is one of the most mutilated and unintelligible kinds of speech. It results from a puncture or fissure in the hard or soft palates, or both, and is frequently accompanied by a split upper lip (harelip). Most cases of cleft palate are congenital, occurring about three times in every one thousand births. Even when the cleft is closed by surgery or by mechanical appliance the individual is likely to remain unintelligible until re-educated by a speech specialist.

Deaf mutism. Individuals born into the world totally deaf to speech sounds never learn to speak unless special methods of instruction are used. According to the Federal Census there is approximately one deaf mute to every 2,355 persons.

Lowered hearing. The hard-of-hearing person is one who learned speech in the normal way, either because his loss of hearing developed after he learned to speak, or because his hearing loss has never been severe enough to prevent him from learning speech in the normal way. Perhaps the most conservative estimate, based on numerous surveys, indicates that one and one-half per cent of the total population have such serious hearing losses that they are significantly handicapped in oral communication, and therefore would benefit by speech correction and by learning lip reading. (See DEAF, EDUCATION OF.)

Spastic speech. This disorder is marked by spasmodic utterance and movements of the speech mechanism and other muscles of the body. It results frequently from birth injury and is one of the most difficult kinds of speech disorders to correct unless given specialized attention during the individual's first decade of life. About seven infants in every 2,000 births are afflicted with spastic paralysis (Little's Disease), three of them dying before they reach the age of four years. Thus, about four out of every 2,000 children of school age are spastic and consequently need expert attention in motor and speech training.

Stuttering. This disorder of speech is marked by hesitancy and repetition in the production of sounds and words and is ordinarily accompanied by tics and involuntary movements. Few speech disorders cause the afflicted person such a constant sense of embarrassment and frustration as does stuttering. About one per cent of the total population is thus afflicted, male stutterers always outnumbering those of the female sex in a ratio of about seven to one.

Dysphonia, disturbance of the voice, is revealed most commonly in hoarseness and whisper-like qualities. The cause may be organic, psychological, or functional, but most kinds of dysphonia are amenable to improvement or correction with the help of the laryngologist and the speech correctionist.

Hysterical mutism is relatively rare except in times of war and other great social crises.

It is often a main symptom of "war shock" (formerly called "shell shock").

Miscellaneous disorders. While such disorders as those mentioned above are surprisingly numerous, there are other kinds, in even greater incidence, which are often referred to broadly as "bad habit" speech defects. Among these are some kinds of lisping, oral inactivity, infantilisms, delayed speech, and sound substitutions. These speech defects should also be treated at the earliest possible time to provide permanent correction and to prevent development of feelings of inferiority. Foreign accent may also be considered in this latter group, since its eradication is based on speech re-education.

Speech Correction Classes. Most disorders of speech are amenable to improvement or correction by re-educational techniques. Many require individualized attention; on the other hand, the large majority, especially those of functional or "bad habit" origin, may be improved by means of class methods. In large school systems it is possible to form small classes, usually no larger than ten members, of children with similar disorders of speech and of similar age. For example, the speech correctionist may re-educate a group of ten-year-old lispingers by calling them to a special class two or three times weekly, and by enlisting the active cooperation of the classroom teacher in holding her students at all times to a reasonable standard of speech. SPEECH EDUCATION. Speech education has become an increasingly important part of curriculum planning within the last twenty-five years. At the turn of the century speech education throughout the United States consisted mainly of courses in elocution, debating (*q.v.*), rhetoric, and public speaking. Such courses were taught primarily in universities and colleges, the University of

Michigan, the University of Wisconsin, Cornell University, and Hamilton College being notable pioneers in this respect. Whatever speech education existed in the secondary schools was of an elocutionary nature. It became apparent eventually that platform address and stage speech were not the only types of oral communication and that adequate private as well as public speech was a necessary attribute of the well-integrated personality. Courses in the speech arts and speech sciences developed with increased emphasis on phonetics, speech pathology, and speech psychology. Although the focus on such courses was in colleges and universities, isolated high schools throughout the country began to expand their offerings in speech, developing especially work in public speaking, debating, and dramatic art. (See DRAMATICS.) At the present time there is still a lamentable lack of uniformity not only in course offerings in Speech of well-established high schools, but also in the requirements for teaching such courses.

Country-wide recognition has been even more dilatory at the elementary level than at the secondary school one. As long ago as 1910 the City of Detroit introduced speech correction into the elementary schools. This program was among the very first in the country. State departments of speech correction were initiated a few years later with the programs of Wisconsin and California. However, only a few states support programs of speech correction. State departments of education, nevertheless, are in many states cognizant of the need for a speech program and are attacking the problem wisely from the standpoint of teacher training. New York, for example, now requires a minimum of 36 semester hours in speech training in the teacher training period of speech teachers.

A recent recommendation, made by a committee appointed by the Board of Education of the City of New York, included the suggestion "that in the future the license to teach speech correction in the New York City Public Schools should be based upon 45 college or university semester credits in speech . . ." This recommendation is representative of a country-wide tendency to raise standards for the training and selection of teachers of speech and speech correction.

SPEECH READING

Many educational systems do not have a corps of specially trained teachers of speech or speech correction. Even so, the need for providing speech education for students is widely recognized. Such cities as Baltimore, Dayton, Buffalo, and Seattle include in the required curricula of the elementary grades practice in pronunciation, oral reading, and public speaking. Hence, the classroom teacher frequently is called upon to give instruction in speech even though she has no specialized training in the subject.

Likewise, in the secondary schools there is lack of uniformity in the offerings in speech education. Frequently, the so-called speech arts—dramatics, choral speaking, oral interpretation, and forensics—are relegated to one speech elective in the senior year of the English classes, to be included along with composition and literature. Many are the secondary schools that would be devoid of speech education were it not for clubs and other extracurricular activities to foster debating and dramatics especially.

Perhaps the greatest growth in speech education within recent years has been effected in the colleges, teachers colleges, and universities. Many of these institutions now have full-fledged departments of speech or speech education with required courses and orientation work in speech for all students. In institutions that offer a speech "major" or concentration the interested student may select courses from three main divisions of speech education:

The Speech Arts, e.g. Voice and Diction, Phonetics, Oral Interpretation of Literature, Choral Speaking, Dramatics, Play Production, Radio Production, Public Speaking, Debating, Group Discussion.

The Scientific Aspects of Speech, e.g. Basic Voice and Speech Science, Psychology of Speech, Experimental Phonetics, Principles of Speech Correction, Practicum in Speech Clinic.

Speech Pedagogy, e.g. Teaching Speech in the Elementary School, Teaching Speech in the Secondary School, Teaching Lip-Reading.

Since the ability to function effectively with a group is a prime necessity for the individual living in a democracy and is significantly dependent upon the ability to speak and listen effectively, it would seem that speech education will continue to grow at all educational

levels. The rapid rise in memberships in The American Speech Correction Association and the The National Association of Teachers of Speech within the last few years would seem to be only one piece of evidence of the decided spread of speech education at the hands of experts throughout the United States.

SPEECH READING. *Speech reading*, more widely though less correctly called *lip-reading*, is the understanding of speech by the interpretation of movements of the lips, jaw, tongue, and throat of the speaker. When speech and speech reading are taught to the deaf and deafened, the *oral method* is said to be used rather than the *manual method*, or sign language.

Speech reading and speech instruction for the deaf were introduced into the United States in 1867, with the establishment of two schools in New York City and Northampton, Massachusetts. Although sign language is still widely taught, it has gradually been displaced by speech reading. Because the former is easier, and thus less expensive, to learn it will probably have a tenacious existence. The quickened interest in speech reading may be attributed in part to the invention of audiometers, machines used to administer objective hearing examinations. As a result of these examinations, estimates are available indicating that more than ten per cent of the school population have defective hearing. Another factor in the spread of speech reading is the knowledge that much defective hearing is progressive, that is, it becomes increasingly severe with advancing age. Hence, many authorities recommend that individuals whose central hearing loss is greater than ten sensation units (a sensation unit [SU] being an audiometric criterion) be taught speech reading along with speech improvement and ear training.

On the whole, the earlier the deaf or deaf-

SPEECH TEST

ened person is taught speech and speech reading, the more satisfactory will be his educational and social adjustment; for it is obvious that the individual who must rely solely on sign language for communication is restricted in his participation in many social activities. Moreover his use of sign language is likely to attract unwelcome attention and curiosity. On the other hand, the use of speech and speech reading provides him with access to a more normal life. Although the ability of speech reading may be acquired successfully at all ages—in one large American speech clinic students of speech reading range in age from three to sixty-three years—some persons learn rapidly, while others require years of intensive effort to become proficient. The extent of the hearing loss, the length of time elapsed between its onset and the inauguration of speech reading lessons, attentive-listening span, intelligence, speech reading readiness, and many other factors are variable determinants of proficiency in speech reading.

There are a number of relatively constant factors that make speech reading difficult. For example, some speech sounds are not visibly produced, such as *n* in the word *fan*; the pairs of cognates *s-z*, *f-v*, *th* (*thin*)-*th* (*thou*), *sh-zh*, etc., are not ordinarily confused by the normal ear, but because they are visually undifferentiated they present difficulties to the ear that does not hear them.

A similar problem is presented by *homophenes*, that is, words that look alike in the speech reading: *pear-bear*, *abuse-amuse*, *ace-haze*, *pat-mat*, etc. Thus, the speech reader must learn to gather fifty per cent or more of his meaning principally from context. Other recurrent irritations to the speech reader are facial impassiveness—or the other extreme, exaggerated “mouthing” of words—in the speaker, poor illumination, extraneous bodily movements of the speaker, technical and unusual words, etc. Because of the many difficulties speech readers encounter, they should be given preferential seating, good illumination, and intelligent consideration at all times.

Notwithstanding such obstacles, speech reading is a real necessity in the education of the deaf and deafened, because with it their hearing appears to improve. Because speech reading lessens mental strain, the speech reader is less likely to suffer from fatigue, and fatigue increases loss of hearing. Speech

reading aids also in the comprehension of partly heard words. Finally, it may be emphasized that speech reading encourages mental stimulation, thus making the afflicted more desirable companions and associates. (See DEAF, EDUCATION OF.) J.F.B.-1

SPEECH TEST. The speech test is ordinarily designed to determine proficiency in the sounds of speech. Speech tests are of three kinds: screening, diagnostic, and achievement. The screening test, although short—taking no more than two or three minutes for each examinee—generally includes oral reading as well as impromptu speaking because some speech disorders, such as stuttering, may be revealed in one and not the other speech activity. The material to be read is composed of vocabulary within the individual’s comprehension. For non-readers, pictures are used instead. The reading material may be artificially loaded with a recurring sound, i.e., *Our chow found the brown trousers down by the fountain*, or may contain words with a casual distribution of sounds. The reading material is often followed by one or more questions designed to encourage impromptu speaking. Such a speech test, when administered by an expert, is adequate for purposes of isolating the speech handicapped.

The diagnostic test requires much more time and includes: (1) an examination of the speech mechanism, namely teeth and occlusion, tongue, hard and soft palates, nasal passages, lips, and glottis; (2) an examination of breath capacity; (3) an audiometric examination; (4) an examination of the individual’s ability to repeat sentences in the intonational patterns rendered by the examiner; (5) an examination of the individual’s ability to use each speech sound in the positions in which it occurs in words and in combinations. Examinations of handedness, intelligence, etc.

are frequently needed to supplement the diagnostic speech test.

The achievement speech test is administered periodically in speech correction classes and clinics that use re-educational techniques mainly. The achievement test, which is designed to determine the progress of an individual undergoing a speech rehabilitation program, is often recorded on a phonographic disc for purposes of motivation and criticism.

The term *speech test* is also occasionally applied to various examinations designed to measure ability in oral interpretation, public speaking, discussion, etc. J.F.B.-1

SPEED TESTS — See STANDARDIZED TESTS.

SPELLING. After forty years of intensive psychological research on spelling, scientifically validated principles of method have not been established and conflict of opinion persists on such major issues as the curriculum and the function of generalization. However, the essential features of a working program in spelling instruction can be delineated.

Spelling vocabulary should be limited to the most important words needed in the writing of children or adults or of both, depending on the educational philosophy of the school. The standard research technique for determining these words is to tabulate the vocabulary of personal and business correspondence, minutes of meetings, children's letters and compositions, and similar writing in terms of such criteria as frequency of use and spread of each word in different types of writing. One master compilation is Horn's "A Basic Writing Vocabulary" of 10,000 words, derived by the author and earlier workers from studies of five million running words of adult writing. McKee's "Children's Writing Vocabulary, Grade by Grade", consisting of 5,000 words culled from three mil-

lion running words, is in process of integration. Since the overlap of both studies is 80 per cent and most elementary schools limit their spelling lists to 4,000 words, a valid and reliable basic list of the 4,000 words common to both, can readily be constructed. For each class, words needed temporarily in connection with projects, activity units, or traditionally organized subjects can be added. The individual pupil can list his own bugbears. However, in schools experimenting with a total experience curriculum, no spelling list is used, so that only words needed in current units are studied.

The grade placement of a given word depends on the level at which children first use it extensively in their writing, on its learning difficulty, and on the frequency of its misspelling. Of these factors only the last has been adequately determined by the construction of spelling scales. The most troublesome words should be repeated within the grade and at higher levels with calculated frequency. As to grouping of words, the preponderance of authority favors grouping by similarity of structure but not by sound except for phonic families; e.g., ate—date, piece of pie, almost—always, all right—all wrong. Though opinion on the grouping of homonyms is sharply divided, it seems sensible to juxtapose them only when the problem actually arises and then to differentiate them by meaning; conversely, teaching pair—pare—pear together merely invites gratuitous trouble.

Extensive research on spelling rules points to teaching each word as an individual problem in the lower grades and the inclusion in the upper grades of very few rules, taught inductively, as supplementary devices to remove real learning difficulties. The rules with fewest exceptions are those governing the formation of derivatives and inflected forms; e.g., words ending in *y* (keys, buried, happier), doubling final consonants (hotter), and final *e* followed by a suffix (ninety, lovable).

The general characteristics of progressive teaching techniques are clearly discernible. With increasing maturity, the learner sees how misspelling weakens effective written communication of thought and experience and he becomes sensitive to the social consequences of poor spelling habits. He understands the

sources of his spelling list, is urged to use the newly mastered words in his own writing, and, in individual study, concentrates on his own errors, with a definite job intrinsically motivated. His interest in and attentive repetition of a comparatively irrational sequence of letters constituting words of an unphonetic language, are sustained by a variety of drill devices, games, and graphs of individual and group progress. Typical devices are word building games, guessing games, use of the typewriter, anagrams, and individual word dictionaries.

About 75 minutes weekly are usually devoted to the thorough study of relatively few words. If grade placement is correct, spelling is directly attacked as spelling, so that other phases of vocabulary study such as word meaning, derivation, and sentence building are admitted only to the extent that they insure correct spelling. Preliminary discussion of the most common difficult spots in the basal list for the unit is followed, as a rule, by a pretest to determine common errors and individual weaknesses. The objection to a pretest on the ground that initial errors persist is not supported by the results of research. As a test, dictation in column form is as effective as presentation in interesting context. Then follow class instruction, supervised individual study, and retesting.

Authorities are in unusual agreement on certain indispensable phases of group and individual study of spelling. A definite, but not ritualistic, method of study should be mastered. It should provide a clear initial perceptual attack, auditory and visual, on syllabic units. It should develop the habit of attention to details, including the writing of the word followed by comparison with the model and several independent attentive repetitions of the last mentioned procedure. It should develop resistance to false analogy (already—alright). With increasing linguistic maturity, especially on the secondary level, should come greater versatility of attack on new spelling problems.

The vital step is supervised individual study. Even on the elementary level few words are missed by fifty per cent or more of the pupils and no one difficult spot is the same for as many as half the class. The individual pupil should be helped to discover the method of independent study optimum for him. It

may be primarily auditory, or visual, or kinæsthetic, or a combination of these; but it must be a definite procedure consistently followed. The learner should develop the habit of checking his written work for spelling, a habit compounded of attention to letter sequence, proof-reading ability, concern over correctness, and comparison with a model such as the dictionary entry. His individual list of misspellings should be checked for correctness and reviewed systematically. The proficient speller should be excused for more productive work.

Retesting should be frequent and cumulative. Mastery of a word should be attested to by correct use in free writing at least three times. Measurement of progress can be achieved only by retesting on the identical words, and not on words of equivalent difficulty selected from a spelling scale.

Children with spelling difficulties can be helped materially only through diagnosis and remedial teaching, the thoroughness of which depends on the extent of their retardation. A pupil's general spelling status can be determined through a standardized test derived from a spelling scale. Analysis of the types of error he makes most frequently on informal classroom tests points to definite remedial instruction. Such types include insertions (athaletic), additions (waite), omissions (wether), substitutions (sity), transpositions (recieve), and phonetic errors (thay). Close observation, especially during supervised individual study, often reveals such factors as an attitude of inferiority toward spelling, general disregard for details, erratic attack on language problems, and poor motor coordination in writing (chothing for clothing). Often these manifestations, concomitants, and causes of poor spelling are effectively attacked by providing pupils with adequate techniques of independent word study, such as recognizing short words within longer ones, and with motivated drill on practice materials directly related to the learner's difficulties, like puzzle games calling for cutting up words into syllables and putting them together again.

Cases of serious retardation require additional study of the whole child as a person and learner. Physical factors, like poor vision; emotional elements; such environmental factors as bilingualism, poor reading, and

word analysis must be determined. The administration and interpretation of a series of diagnostic tests, like the "Gates-Russell Spelling Diagnosis Tests", though time consuming, reveal points at which learning breaks down and indicate the need for a differentiated remedial program, which capitalizes on whatever compensatory "abilities" in spelling the learner has so that he may develop a satisfactory method of study and a positive attitude toward solving his spelling problems. SPELLING, PHONETIC. Almost any letter in the English alphabet represents from two to eight different sounds, with the eight long vowels recorded in sixty-six different spellings (*sh* in *share*, *sure*, *schist*, *chef*, *ocean*, *nation*; *a* in *make*, *sail*, *weigh*, *steak*, *gauge*, *gaol*, etc.). Ideal for children and foreigners studying English would be a system of spelling in which each letter represents only one sound. Such a system is the International Phonetic Alphabet, but it has slight chance of general adoption because it transforms the general appearance of the printed page, impedes efficiency in silent reading by encouraging vocalization, entails enormous expense in reprinting books, and is too radical for lexicographers, teachers, and publishers of manuals of style.

Of the plans for simplification offered since the 16th century, the most promising is that of the Simplified Spelling Board, many of whose recommendations are included as alternative or even preferred spellings in such dictionaries as the *Century*, *Funk and Wagnall's Standard*, and the second edition of *Webster's New International* (1934). The most important suggestions include simplification of digraphs (*caracter*, *cigaret*, *glas*, *helth*, *laf*, *senery*), elimination of silent *e* in certain groups (*giv*, *engin*, *traveld*), elimination of other silent letters (*det*, *catalog*, *tho*, *thru*, *bild*, *gost*, *crum*), reduction in number of spellings for the same sound (*chief-receiv*,

precede-procede), elimination of troublesome spellings of unaccented vowels (*forfit*), elimination of duplications (*theater-theatre*), and other modifications toward phonetic or uniform spelling (*esthetic*, *advize*, *tipe*).

Admittedly any such moderate program of reform fails to solve the basic problems of consistency, especially as to doubling of consonants, and of substitution of one method for the traditional five for indicating vowel length, particularly with reference to final silent *e*. The elimination of the more troublesome inconsistencies, such as the plural forms of words ending in *o* (*solos*, *Negroes*), is likely to be adopted more readily than changes that violate traditional principles of English spelling. S.S.

SPENCER, HERBERT (1820-1903).

Spencer has an important place in the history of nineteenth century thought in many fields. He attempted a synthesis, or *Weltanschauung*, in which the evolutionary hypothesis developed in biology by Wallace, Darwin, and others was carried over into the social sciences, especially into the fields of ethics, sociology, and education.

In its educational application, Spencer's work was pointed toward several related objectives. The first of these was to sound a clarion call to the leaders of English education to reflect in their curricula and methods the scientific achievements of the first half of the nineteenth century; it was a throwing down of the gauntlet to those who placed the humanities at the focus and periphery of the English "public" schools, to the almost complete exclusion of the sciences. These were the schools then preparing the prospective leaders of English society. Spencer was chagrined that the great advances in pure science (in astronomy, geology, biology, and physics) and the epoch-making improvements resulting from applied science (manufacture, transportation, communication, and the relief of suffering) should find no echo or recognition in contemporary English education.

A second objective that tintured his educational theory was the attempt to reinterpret the purposes and procedures of education in

terms of the evolutionary hypothesis. A third objective, albeit probably less conscious in his work, was to restate some of the educational ideas of continental thinkers, especially of Rousseau (*q.v.*) and Pestalozzi (*q.v.*).

The main vehicle through which Spencer established his influence on English education was a group of four essays, separately published in periodical journals between 1854 and 1859, and published in book form in 1861 under the title *Education; Intellectual, Moral, and Physical*. Their great influence rested partly on Spencer's power to combine a rich fund of scientific information with unusual power of exposition.

"What Knowledge Is of Most Worth?" was the title of the first and most important of the four essays. In it Spencer set up the ultimate aim of education as complete living. Next, he analyzed complete living into its five cardinal elements: direct self-preservation (health); indirect self-preservation (earning a livelihood); parenthood; citizenship; worthy use of leisure. For each of these areas he argued the superiority of the sciences over the humanities then entrenched in English secondary schools. With great rhetorical effectiveness, he presented his polemic, not for an equivalence of the sciences, as was the case with Eliot (*q.v.*) in America, but for their hegemony in the curriculum.

In the course of this brief for the sciences, Spencer extended the denotation of the term where it served the purposes of the argument. Thus, psychology was adduced as an indispensable science for the complete living of the parent, and sociology as an indispensable science for the successful earning of a livelihood in an England which was becoming rapidly industrialized.

Following the brief for the sciences on inherent content grounds, Spencer argues for them as superior to the prevailing humanities on disciplinary grounds—their value in training the memory, the understanding, the judgment. He argued their superior merit in fostering independence, also in generating respect for the laws which underlie all phenomena—a contribution to the development of religious character.

Intellectual, Moral, and Physical Education. The three other essays contributed little that was new to the stream of educational thinking, but they did restate positions earlier maintained by important educational

leaders. Thus, the essay "Intellectual Education" was a needed restatement of some of the main Pestalozzian tenets (See PESTALOZZI), and of the culture epochs (*q.v.*) theory, one of the most curious and persistent bequests of the evolutionary hypothesis to curriculum thinking. The essay "Moral Education" resurrected for many readers the doctrine of natural punishments (*q.v.*), previously preached by Rousseau (*q.v.*). "Physical Education" stated many common sense rules as to diet, clothing, and exercise, and cogently attacked the "hardening process," which had been urged by Locke and later by Rousseau.

Spencer must be given a place in the history of the movement to broaden the curriculum, especially in the movement to admit the sciences to the curricula of secondary and higher education. He would have them admitted not on sufferance, but on their own merits as bearing on modern living, interpenetrated as it is by pure and applied science. P.R.V.C.

STANDARDIZED TESTS. Tests are said to be standardized when they have been so constructed that they can be administered and interpreted under uniform conditions. The terms *standardized tests* and *standard tests* are often used interchangeably. Standard tests are widely employed today for measuring various aspects of educational achievement and of intelligence. They are also used

STANDARDIZED TESTS

less extensively for measuring numerous traits of personality and character.

Standard tests may be classified in several ways. According to method of administration, tests are either individual or group tests. According to function measured, tests may be classified as intelligence or mental tests, achievement or educational tests, and character and personality tests. (See **ACHIEVEMENT TESTS, CHARACTER AND PERSONALITY TESTS, INTELLIGENCE.**) On the basis of content, intelligence tests may be further subdivided into verbal, and nonverbal or performance tests. According to scope, standard tests may be classified as general or specific. For example, a general test of intelligence affords an all-round measure of learning capacity, while an aptitude test measures learning capacity in a specific area such as algebra or music. In like manner, a survey test is a test of general achievement, and is different from a practice test or a diagnostic test, the scope of the latter two tests being more restricted.

From still another point of view, tests may be classified as speed tests or power tests. In a speed test, the items are of equal difficulty and are administered with short time limits in order to test the speed of the learner's responses. Speed tests are important in skill subjects, such as handwriting, typing, shorthand, etc. A power test is one which measures the level of difficulty of the tasks that an individual can perform in a given field, without regard to time. Most standardized tests are scaled, that is, the items are arranged in order of increasing difficulty, and time limits are set for the entire test or for each part of the test.

A standardized test of school achievement differs from an ordinary teacher-made test in four essential respects. In the first place, the content has been standardized. This means that each item has survived most careful scrutiny by competent persons, and that its difficulty and value have been determined by rigid experimental processes that have eliminated its weaker fellows. In the second place, its method of administration has been standardized. This means that definite directions have been worked out, usually with appropriate time limits and the like. In the third place, the method of scoring has been standardized. This means that scoring keys have been prepared and that definite rules have

been formulated for marking the papers and for determining the scores on each part and on the test as a whole. Finally, the process of interpretation has been standardized, at least in part. This means that tables of comparative data are available for interpreting the various scores made on the test. These data, or norms (*q.v.*), are usually the average scores which have been made by large numbers of pupils, distributed over wide geographical areas and representing various types of schools. These average scores are grouped, as a rule, according to chronological age or school grade.

Because standardized tests have the merits of a carefully selected content (the difficulty and the value of which have been determined experimentally) and of norms to facilitate interpreting the scores, they are likely to be superior to nonstandard tests for comparing the achievements of a student or a group, with the achievements of other students either in the same school system or elsewhere. The very standardization of content, administration, and interpretation which makes these tests so useful for comparative studies also detracts from the flexibility of the tests so that they may not be well adapted to situations which depart widely from those of the typical school. This inflexibility need not be an insurmountable obstacle, however, since a test may be standardized on the basis of local conditions, especially if the school or the school system is large enough. The *Metropolitan Achievement Tests, New York City Edition*, for example, have been designed specifically to meet the needs of the New York City schools. As a rule, a complete program of measurement will require the use of nonstandardized tests as well as standardized tests. The outstanding advantage of informal, nonstandardized tests is that they are highly flexible and can be tailor-made to fit local conditions. Their construction, however, requires considerable time and skill.

Standardized tests have many functions: among these the most important are the administrative, instructional, and research functions. The administrator may use these tests as a basis for the classification and promotion of pupils, or as an aid in the evaluation of teachers and school programs. The teacher may see these tests as valued guides in educational diagnosis, as a source of student moti-

vation, or as a means of assigning marks. To the research worker, the standardized test may be used as a means of measuring student growth under varying conditions. To be sure, these illustrations merely exemplify the varied ways in which standardized tests are used; they do not indicate all of the functions these tests can serve. To some extent, tests used for these various functions are actually different tests. Survey tests, for example, are more likely to be used for administrative than for instructional purposes, whereas diagnostic or practice tests are chiefly instructional. Which tests the research worker will use depends largely on the specific problem with which he is concerned. Many tests may serve all three types of functions. Survey tests, for example, may be used for motivating learning, for classifying pupils, and for measuring the achievement of large numbers of pupils.

STANDARDS OF ACHIEVEMENT.

It is a common educational practice to provide, for administrative purposes, measures of pupil achievement on the basis of 100 per cent (presumably representing perfection). The "passing" mark is usually not less than 60 per cent nor more than 80 per cent. Not uncommonly, letters are used to represent achievement, such letter grades, however, being based originally on per cent marks. The percentage that is regarded as a passing grade varies considerably in different countries; in England, for example, the passing mark is normally about one-half as high as that used in this country.

There are several assumptions underlying the practice of using 100 per cent as perfection and of having a "passing" standard. First, pupils must be labeled as having passed or failed in the sense that they have learned enough or not enough of a given subject. Secondly, such a mark represents an amount of achievement; for example, 70 per cent

signifies seven-tenths of perfection or of the maximum amount and quality that should be expected. Thirdly, such a mark is a good measure of what is adequate or inadequate achievement. And finally, such measures are assumed to provide a sound basis for determining whether pupils should be promoted or certified.

The use of letter grades such as *A* to represent 90 per cent or over, *B*, 80 to 89 per cent (and in more recent years terms such as *H*, *S*, and *U* for *honor*, *satisfactory*, and *unsatisfactory*), and so on, indicates dissatisfaction with the per cent method of evaluating pupil achievement. The hundred per cent standard, although apparently definite and objective, lacks significance. Perfection in achievement in a school subject can hardly be expected; and there is obviously marked disagreement on what would constitute maximum expected achievement.

In like manner, although a passing mark of 70 per cent (or a similar value) has the appearance of definiteness and objectivity, it is actually arbitrary and lacking in significance. There is no basis for deciding that adequate achievement is 50 or 60 or 90 per cent of a presumed 100-per-cent achievement. The significance of such a passing mark is further reduced by subjectivity both in what it represents and in the methods used in evaluating pupil achievement.

There is virtually no objective and accurate basis for determining standards of achievement in school work. Objective tests of various sorts are accompanied by norms (*q.v.*), which represent typical achievement. Norms are not standards and do not represent expected achievement. They cannot be used as standards until they are evaluated in terms of criteria of expected achievement—criteria that do not exist. It is probably not incorrect to state that up to the present the educational processes in our schools have not been based on sound standards of achievement. In other words, it is not possible to state, for example, in terms of experimental evidence, that after a pupil of a certain age, ability, and background has experienced a certain amount and type of learning, he should have acquired certain specified learnings. There is now, and always has been, a serious need for determining standards of achievement. Without them there is a lack of real knowledge of the kind of learning the pupil has actually

STATE AID

acquired—corresponding in definiteness, for example, to the achievement in typewriting that is characterized by the ability to type forty words a minute with one error per 150 strokes in typing straight matter without numbers and characters, of a specified syllabic intensity.

The problem of standards of achievement is further complicated by the question of whether standards should be in terms of immediate learning or the residuum at a later date. Entirely apart from the influence of forgetting, the achievement some time after the original learning took place may be markedly less than the immediate achievement, depending upon the nature of the original learning. Where meaning does not exist and the learning is entirely rote, sheer drill may produce apparently good achievement. After a comparatively short time, almost none of this "learning" may remain. Moreover, it is not the amount the pupil learned at the time the learning took place but the amount he has available for use when it is needed that probably gives a truer picture. The usual school grades therefore offer only an inadequate, and sometimes an invalid and unreliable, measure of the student's abilities and potentialities.

J.S.O.

STATE AID. The term *state aid* refers to the payment of funds from state sources to assist in defraying the expenses of maintaining public or private schools of elementary, secondary, or collegiate grade. In all states of the Union a portion of the financial support for public elementary and secondary schools is derived from state sources. State controlled colleges, universities, and special schools are financed largely from state funds. In some cases, a relatively small amount of state money is paid for the support of privately controlled schools.

Historical. The principle of state aid for schools dates from the establishment of permanent school funds derived from the proceeds of sales of school lands and money grants made to the states by the federal government. The admission of Ohio in the year 1802 marked the beginning of this policy, although state support had its roots in much earlier times. For a time after the establishment of permanent school funds it was hoped that receipts from this source would in time support all the needed schools. It soon be-

came evident, however, that this hope was not to be realized and that the states through taxation must aid in the support of education. The slogan "the wealth of the state must educate the children of the state" was recognized as early as 1825, although it was not until much later that the states through taxation made any considerable contribution to the support of the schools. Not until recently has this support been considered in any way adequate, and even today it is very small in some states.

During the period from 1890 to 1938, school support from permanent funds and land leases decreased from 5.4 per cent to 1.1 per cent of all revenue receipts. Although the amounts of money increased, total school costs increased so much more rapidly that the decrease in percentage was the result. Receipts from state taxation and appropriations decreased from 18.4 per cent in 1890 to 13.8 per cent in 1920, but increased after that year to 28.5 per cent in 1938.¹

Amount of State Aid. In 1938, state aid for public elementary and secondary schools was derived almost entirely from taxation and appropriations, from permanent school funds (mostly state), and income from school lands. The total amount reported from these sources was \$656,744,116 or 29.6 per cent of all revenue receipts for schools. The amount and percentage from each source is shown in Table I.

TABLE I
Amount of State Aid in 1937-38¹

Sources of State Aid	Amount	Percentage of All School Revenue
Permanent School Funds and Lands	\$ 24,029,905	1.1
Taxation and Appropriations	632,714,211	28.5
Total	\$656,744,116	29.6

Although the percentage of state school revenue derived from taxation and appropriations for the nation as a whole is substantial, there is great variation among the states. In 1938 there were ten states in which state aid from this source amounted to more than 50 per cent of the revenue receipts for schools. Delaware was highest with a percentage of 92.8. At the same time there were thirteen states in which state aid from this source contributed less than 10 per cent of the school revenue. Oregon and Colorado were lowest with percentages of 0.2 each. As sources of

state aid, permanent school funds and land leases provided 17.1 per cent in New Mexico and 15.6 per cent in Wyoming, but in thirteen states there was no school income from this source. For the nation as a whole, the contribution was 93 cents per pupil enrolled.¹

State aid, or moneys derived directly from state governments for the current maintenance of 586 publicly controlled colleges and universities, including teachers colleges and normal schools, amounted, in 1938, to \$133,448,299 or 50.9 per cent of the income of these schools. For 1,000 privately controlled colleges and universities, state aid during the same year amounted to \$7,510,824 or 2.9 per cent of their income. For the entire group of publicly and privately controlled institutions, state governments contributed 27.0 per cent of the income.¹

The constitutional or statutory provisions of many states prohibit the use of public money for sectarian private schools. In a number of states a relatively small amount of state aid is paid to schools under private auspices. Maine grants state aid to privately controlled academies and in several other states elementary or high schools operating under the cooperation of the church and public authorities receive some public funds. Indirectly, public support is given to private institutions by exempting the property of such institutions from taxation. On the other hand, many private institutions contribute much more to public welfare than they receive through tax exemption. Some states provide for free textbooks and free transportation for children attending private schools.⁴

Distribution of State Aid. As soon as the states began to raise money for schools on a state-wide basis they were faced with the problem of how to distribute such funds. Through more than a century of experience with various distribution plans, a number of methods stand out as those most frequently used. Three of these are the distribution of state aid on the bases of need, reward for effort, and equalization.

The basis of distributing state aid according to need takes into consideration only the size of the educational task in a community as measured by the number of pupils on the census rolls, the number enrolled, the number in attendance, the number of teachers employed, or the number of schools maintained.

This basis is also known as the "flat grant" method of distribution. It has persisted throughout the history of state support and remains today as one of the most frequently employed bases of distribution.

The reward for effort basis recognizes the need for the state to subsidize special community educational undertakings and to distribute a portion of the state aid as special subsidies. There are many forms of such special aids today as, for example, high school aid, consolidated school aid, textbook aid, transportation aid, vocational class aid, and aids for various other types of special educational projects.

The equalization basis for the distribution of state funds recognizes the need for greater equality in the support of schools. In its use funds are distributed in such a way as to permit all districts or counties to maintain a satisfactory foundation program of education without exhausting the tax resources of the community. Measures of need and ability to pay are employed in such a manner as to permit greater state aid quotas to the poorer districts and smaller quotas to the wealthier ones. When the local units can qualify for equalization aid without exhausting their local tax resources, the remaining tax leeway may be used for the improvement of the local educational program above the minimum required. Although this basis is relatively new there has been much interest exhibited by the states and many have adopted plans for the distribution of all or a part of their state aid on this basis.

State Centralization and State Aid. As the proportion of state aid to schools has increased, the question of the effect of such increased aid upon centralization of the control of education has been raised. There are those who hold that state centralization will be the result of increased state aid. Because they fear highly centralized control of the schools, they oppose increased state aid. Opposed to this contention are those who hold that the support of education and its control are entirely separate and that control need not and does not follow the dollar. According to this view of the separability of control and support, the allocation of the controls between the state and the local district need not be influenced by the source of the support. It is entirely feasible to have local control

STATE BOARD OF EDUCATION — STATE COLLEGES

with state support, or local control with local and state support, or, again, local and state control with local and state support. The practice in most states is to give both the local school districts and the state certain responsibilities in the control as well as in the support of education. (See FINANCE, SCHOOL; FEDERAL AID TO EDUCATION; STATE CONTROL OF EDUCATION; SUPPORT OF EDUCATION.)

STATE COLLEGES AND UNIVERSITIES. State colleges and universities comprise those institutions of higher education directly under the control and support of the states. Four principal types or groups of schools are included: (1) state universities, (2) land-grant colleges, (3) professional schools, and (4) junior colleges. Some of these institutions, especially the junior colleges, are under the control of municipalities; but are here classed as state schools. Privately controlled colleges and universities, even though they receive some state support, are not regarded as state schools.

Historical. State colleges and universities in America arose during the early years of the national period. While they had their beginnings in the privately controlled colonial colleges, great impetus was given them through the ordinance for the disposition of the lands in the Northwest Territory in which land grants were made for state universities. The earliest of these was made in the state

of Ohio, in which two townships of land were reserved for a state university. Public-land states admitted after 1802, the year in which Ohio was admitted, received at least one township of public land for seminaries of learning or universities. (See LAND GRANT COLLEGES.)

In the Constitutional Convention of 1787 an effort was made to embody provisions for a national university. Although the provisions were not adopted and subsequent agitation for this project was ineffectual, the attempt shows the interest of the founders of the Constitution in higher education. Instead of one National University, the states were to have their own state colleges and state universities.

It is difficult to trace the rise of state universities since a number of them began as private institutions and were later brought under state control. Several were founded during the colonial period only to pass out of existence in later years. The University of North Carolina, chartered in 1789 and opened in 1795, is one of the earliest of these institutions to survive as a present-day state university. Others were the University of Vermont, organized in 1791 and the University of Virginia, organized in 1815³.

The Morrill Act of 1862, which provided federal aid to the states for colleges of agriculture and mechanical arts, gave impetus to the establishment of many such institutions through the nation. In some states separate institutions were established, whereas in other states, colleges of agriculture and engineering were made an integral part of state universities. Through subsequent legislation providing for additional federal funds to the land-grant colleges and universities, these schools have been developed until today there are 69 such institutions. Of this number 24 are separate colleges; 28 are universities in which work in agriculture, engineering, and home economics forms a part of the work of the institutions; and 17 are institutions of higher learning devoted to education of Negroes.⁴

The development of professional schools is difficult to trace since many of them were established as parts of state or private colleges and universities. Any listing of separate professional schools would be quite incom-

STATE COLLEGES AND UNIVERSITIES

plete. The one outstanding group is the state teachers colleges and normal schools (See NORMAL SCHOOLS and TEACHERS COLLEGES).

The public junior college, which is generally regarded as an upward extension of the secondary school, is distinctly a development of the first quarter of the twentieth century. The oldest public junior college still in existence was established in Joliet, Illinois, in 1902. California enacted a state junior college law in 1907 which authorized boards of education to prescribe courses of study to approximate the work of the first two years of the university course. Similar laws were subsequently enacted in other states.

State junior colleges constitute a group of organizations such as lower divisions in state universities, branch colleges operated in cooperation with state colleges and universities, normal schools accredited for two years, and a number of experimental units in connection with state colleges and universities.³ (See JUNIOR COLLEGE.)

Number, Staff, and Enrollment. The Biennial Survey of Education for 1937-38 gives statistics for publicly controlled institutions as follows: 138 four-year colleges, universities, and professional schools; 160 teachers colleges; 93 normal schools; and 209 junior colleges. The total of 600 represents practically all of the publicly controlled institutions of higher education in the United States. Compared with the 1090 privately controlled colleges and universities reported in the survey, the public ones comprise about 36 per cent of the total number.¹

The total number of faculty members including administrators, teachers, extension and research workers, and other professional personnel, but not including clerical and custodial help, equated on a full-time basis, for the 600 publicly controlled institutions was 58,490, of whom 40,621 were men and 17,869 were women. Resident institutions claimed the service of 46,641 persons; the remainder were engaged in extension work, research, etc.

The total resident college enrollment during the regular session 1937-38 was 689,483,

of whom 402,902 were men and 286,581 were women. About 57 per cent of all college students were enrolled in the publicly controlled institutions. In addition to the enrollment in the regular session, there were 262,012 students enrolled in the summer session of 1937, of whom 96,731 were men and 165,281 were women. Approximately 52 per cent of the undergraduate students enrolled in regular sessions were in professional schools and 48 per cent in the arts and sciences. Approximately 95 per cent of the students are undergraduates and 5 per cent, graduates.¹

Financial Support. Approximately one-half of the income for maintenance of publicly controlled colleges and universities was derived from state governments. The ten per cent of the total income that came from the Federal government was largely from appropriation made to the land-grant colleges and universities, and the 8 per cent of the total income that was derived from local governments represents local support for municipal and junior colleges. Student fees comprised approximately 18 per cent of the income. Table I shows the amount and percentages of income from various sources for 586 publicly controlled colleges and universities in 1937-38.¹

TABLE I
*Income of Publicly Controlled Colleges
and Universities*

Source	Amount	Percentage
Income for Educational and general purposes:		
Student fees	\$ 46,961,517	17.9
Endowment earnings ..	5,931,479	2.3
Federal government ..	27,202,464	10.4
State government	133,448,299	50.9
Local government	21,894,104	8.3
Private gifts and grants	4,535,238	1.7
Sales and services, related activities	16,941,320	6.5
Miscellaneous	5,321,792	2.0
Total	\$262,236,213	100.0
Receipts for addition to physical plant:	\$ 39,511,416

STATE DEPARTMENT OF EDUCATION. Any specific statement descriptive of state departments of education in the various states is difficult because of the lack of uniformity in the legal provisions and terminology used in designating the department. All states have some agency which may be described as a state department of education and which consists essentially of a staff of assistants to the chief educational officer of the state.

Functions. In theory, the state department of education exercises some six functions as follows: general supervision of the school systems of the state; assistance to the local school units; coordination of educational activities and enterprise; appraisal of the effectiveness of the school program; conduct of research; and advice to the governor and the legislature on educational legislation.¹

In addition to these major functions, state departments of education carry on a wide

range of specific administrative and supervisory functions, some of the more important of which are: supervision of vocational education, supervision of elementary and secondary schools; certification of teachers; approval of school building plans; provision for library service; vocational rehabilitation; rural school supervision; construction of courses of study; making school surveys; and improvement of instruction.

Organization. The organization of state departments of education varies greatly among states and depends largely upon the size of the staff and the functions it undertakes.

In 1936, one state had fewer than ten members on its state department staff, whereas ten states had sixty-one or more. There is a tendency to organize state departments of education on the basis of the major functions which they perform. An example of such a functional organization is that of the state of Maryland in which there are fourteen departments, each of which is headed by a supervisor or director. Some of these departments are as follows: supervisor of physical education; supervisor of vocational rehabilitation, special education and attendance; supervisor of agriculture, part time; home economics supervisor; director of vocational education and supervisor of industrial education; supervisor of high schools; supervisor of elementary education; assistant superintendent in charge of elementary education; supervisor of Negro schools; credential secretary and office manager; financial secretary; consultant architect.¹ State departments should be so organized that there is some person or agency equipped to assist the schools in any type of problem that may arise.

State superintendent. The chief state school officer, or state superintendent, heads the state department of education and serves as its executive officer. All states in the Union provide for such an officer. The office of state superintendent is provided by law and may be more or less closely associated with the state board of education. In thirty-two states this officer is elected by popular vote, in eight states he is appointed by the state board of education and in eight states he is appointed by the governor. There is quite general agreement among school administrators that the state superintendent should be removed from partisan politics and should be

STATE EXAMINATIONS

selected and appointed by the state board of education in the same manner as city superintendents are appointed.

In states that elect state superintendents by popular vote the most frequent length of term is four years. Fourteen of the states have terms from one to two years and seven have possible terms of more than four years. In those states in which the officer is appointed, he may serve, in some cases, for an indefinite term.

The duties of the state superintendent vary greatly according to the statutory provisions of the particular states. In some states he has general supervision of the schools but has relatively few specifically delegated administrative and supervisory responsibilities, whereas in other states his duties are more numerous and more definitely defined. (See also BOARD OF EDUCATION, STATE; STATE SYSTEMS OF EDUCATION.) W.C.R.

STATE EXAMINATIONS. A study of state-wide examinations reveals a wide divergence of practices in elementary and secondary schools. An attempt to classify examination practices has been made in studies carried on by the Office of Education. Descriptions of the practices in the various states are also given in order to show how examinations are constructed, administered, and used.

Elementary School Examinations. Elementary school examinations on a state-wide basis are usually graduation or leaving examinations; those given at the close of the work of the eighth grade. Eleven states have local freedom in the matter of examinations; sixteen states have county dominance, or examinations given in some or all of the counties under the initiative and direction of the county superintendent; and twenty-one states have state controlled or state dominated examination systems.¹

The types of examinations used in state testing programs may be of four types: locally constructed non-standardized, locally con-

structed partially standardized, nationally standardized achievement tests, and nationally standardized general mental ability tests.¹ (See STANDARDIZED TESTS.) Examinations are usually administered locally, scored by state or county agencies, and the results used for marking, or promotion to high school.

High School Examinations. Although state examinations in some form have been in use for sixty years or more, the modern conception of cooperative testing is of relatively recent origin. This conception of testing over a wider area than the local school system has grown in popularity since it affords a basis of comparison of achievement with comparable schools. It is also recognized that cooperative testing in states or regions provides a better basis for comparison of schools than do national norms because of the regional differences that exist among schools. (See also NORMS.)

In 1933 there were sixteen states that had developed state-wide testing programs and two states that had state testing service for non-accredited high schools. A number of different types of testing programs are maintained on a state-wide basis. Montana, Colorado, Kansas, Iowa, Indiana, and Ohio maintain their own state programs and promote individual and school competition. Programs in Michigan and New Hampshire are maintained as services to schools without emphasizing competition. The programs in North Dakota and Texas are for non-accredited high schools. Other states, including Minnesota, North Carolina, and Wisconsin, have developed programs of general scholastic aptitude testing, largely for the benefit of cooperating colleges and universities. Part of the Ohio program is also of this character. The programs in Maine, New York, Georgia, Alabama, and in part that in Pennsylvania, have been directed toward the supervision of high school instruction.²

The general purposes of state-wide testing programs may be stated as the following: motivation, emphasis on reasoning, college entrance, guidance, supervision, and research. The tests for the high school testing programs are carefully constructed by states and national agencies. They are provided in several forms.² (See also REGENTS EXAMINATION.) W.C.R.

STATE SYSTEMS OF EDUCATION

STATE SYSTEMS OF EDUCATION.

By virtue of the tenth amendment to the Constitution of the United States, there is reserved to each state the right and the responsibility to organize its own system of public education. Because of this individual authority there developed from the beginning a wide diversity of practices and policies. In more recent years there has come about an increasing similarity in general practices, though they still differ in many aspects of administrative practice and finance.

The system of education in a majority of states had its official origin in the appointment or election of a state school officer, known by some such title as Superintendent of Public Instruction or Superintendent of Schools. He usually took over the work, mostly clerical in nature, previously performed by some other state officer.

While the responsibility of a state for the education of its youth is made clear in most state constitutions, or by legislative act, much controversy has resulted in the exercise of this responsibility, particularly in the matter of state vs. local control of schools. Doubtless this was occasioned often by the fact that communities early developed their schools through local financial support prior to the time that state superintendents' offices came into effective being.

The general trend toward strengthening the power of the executive branch of the state government has resulted in a concomitant growth of increasing authority and control of state departments of education over school policies and procedures. Numerous powers, formerly exercised by local school authorities, have now been taken over in different degrees by the various state officials. Among these powers are: (1) certification of teachers, supervisors, superintendents, and special agents of the schools such as school psychologists, visiting teachers, school counselors, etc.; (2) accrediting of various local schools within the state—secondary schools must meet standards

established by the state in order to be accredited institutions; (3) approval of school building plans before the locality can proceed with construction; (4) enforcement of compulsory school attendance requirements as specified by law, instead of relying solely upon the locality for the enforcement of these regulations; (5) supervision of instruction; and (6) provision for courses of study that must become the basis of the locality's school program.

This tendency in the direction of state control of education has been accompanied by a movement for wider state support of education, which is but a phase of the whole movement in the direction of a greater exercise of state control over education. It is axiomatic in the field of school finance that local communities are most unequal in their ability to support educational programs for the development of their peoples. If therefore, the state is to demand of its local communities that certain standards be met, it becomes the obvious obligation of the state to come to the financial support of those communities unable to meet these demands. (See SUPPORT OF EDUCATION.)

Certain general trends seem to be emerging in the administration of state systems of education, as, for example, (1) the demand for a nonpolitical, strong state board of education, (2) the tendency to have the state board of education take over educational functions previously administered by separate boards (e.g., vocational education), (3) a greater participation by the state in the financing of local schools, (4) the consolidation of smaller local school districts, and (5) a greater measure of professional leadership emanating from the state departments of education.

In most of the states there exist separate boards for the administration of public elementary and secondary education, and for the administration of public higher educational institutions. In only a few states is the general administration of public schools and higher schools vested in one board. In fewer states still is there found a single board for the administration of all higher educational institutions.

In practically all states there are local boards whose function it is to administer the school policies of the local area. Each of

STATE SYSTEMS OF EDUCATION

these local and state boards—elective, appointive, or ex-officio—is charged, by legislative enactment generally, with certain duties and responsibilities which vary greatly among the different states and even within the same state.

Characteristic differences in state systems of education include such factors as: (1) the varying plans for financing schools, involving the relative contribution made by the state, the local district, and intermediary units, as the county, township, parish, etc.; (2) the relative effectiveness of the over-all administrative and supervisory function of the office of the chief state school officer and his departmental staff; (3) the type and number of boards of education and the relative legal authority and responsibility carried by each, both within a state and between states; and (4) the type of school district organization, whether primarily on a local district basis, on a state basis, or built upon such intermediary-size units as the county and similar areas within a state.

Characteristic similarities in state systems of education include: (1) customarily, some type of state board of education that possesses general jurisdiction over public schools within the state; (2) a chief state school officer, either elected or appointed, who serves in the general capacity of executive officer of the board in exercising professional leadership as regards the public school program with the aid of his staff which is usually organized on a functional basis; (3) local area public school boards of education, elected or appointed, which function in a somewhat similar capacity in most states in the establishment of local school policies; and (4) a fairly common division of the school program into elementary, secondary, and higher education, though the number of years in the elementary school program varies somewhat, particularly in the South where a number of states operate a seven-year program.

The conclusion is somewhat inevitable that there is no national system of education in the United States but rather some forty-eight different state systems, with certain similarities and with rather widely divergent differences.

There are many ways in which private school officials cooperate with public agencies and their representatives in promoting the

common welfare of children in the state. For instance, statistical information is supplied to state school officers, educational campaigns are organized to promote child health, attendance regulations are enforced, safety regulations and the requirements of the state building code are observed, and drives for special purposes are carried on during designated periods.

Private elementary schools and secondary schools are subject to certain legislative requirements, most of which also affect public educational institutions. Examples are the compulsory school law; the teaching of American history, civics or citizenship, and the Constitution; the use of the English language; salute to the flag; the loyalty oath; fire drills; length of school year and instruction in hygiene or fire prevention. Lischka's *Private Schools and State Laws* lists the states (number indicated in parentheses) that have laws and constitutional provisions affecting private education: compulsory attendance (48); inspection and supervision (23); general curriculum (29); teaching the Constitution, civics, and patriotism (24); English as the language of instruction (29); qualifications of teachers (11); reports (27); medical inspection (5). Teaching certificates are required in four states: Alabama, South Dakota, Michigan and Nebraska. A certain degree of supervision is exercised over private schools by state accrediting systems covering colleges and secondary schools. Official approval is granted on the basis of ability to satisfy such standards as training and experience of faculty, library and laboratory facilities, curricula, plant, etc. New York requires private elementary and secondary school students to take the Regents' examinations in basic subjects. The private school teachers are granted the privilege of administering and grading the examinations, subject to review by the State Department of Education. Gabel says, "In the past, State supervision of private schools on the lower level has been at a minimum, but the tendency towards increasing control is noticeable and has the approval of many public school educators."

STATISTICAL INFERENCE. When statistics are computed which have as their purpose a description of a sample, such as means or standard deviations or coefficients of correlation, no inference is involved because the generalizations do not go at all beyond the data of the sample. But frequently we wish more than a description of a sample; we wish to estimate from the data of the sample the standard deviation or the coefficient of correlation or other parameter of the population from which the sample was drawn; or we wish to infer characteristics of the distribution of statistics from samples, such as the standard error of the mean, from data within the single sample in hand, or to estimate other relationships. In all of these cases we generalize beyond our data—we infer. R. A. Fisher and his disciples have recently given much attention to the method of determining statistics that are most consistent and efficient for purposes of statistical inference.

STEALING. Stealing ranks high in the list of juvenile offenses, being the most frequent offense for boys. Its seriousness may vary from petty pilfering to burglary and armed robbery; it may be occasional or habitual; and it may be committed by an individual or a gang.

Until the age of three the child has difficulty in distinguishing between what belongs to him and what belongs to others. With adequate training and guidance, however, most children should have definite ideas of property rights by the time they enter school. Nevertheless, some may not develop this understanding until later, and these often cause many problems in school.

Since honesty is an acquired, not an inherited characteristic, the reasons for stealing are many and varied—home training may be poor, or, in families low on the economic scale, stealing may be an accepted method of supplementing income. The child who sees other children with toys and spending money he lacks may steal to procure them. The diabetic youngster may steal to buy the candy he craves but is forbidden to eat. The child who feels inadequate, not liked by other children, not secure in his acceptance by others, may steal in order to buy his way into a group, hoping in that way to secure acceptance, gang approval, and some attention. Of major significance is theft as a manifestation of a neurotic disturbance. It may be one of the devices used by an emotionally upset child to ease his guilt because of sex phantasies, masturbation, or similar guilt producing situations. Mental conflict may lead a child to compulsive stealing, which causes him great distress but which he is unable to control.

Undoubtedly, the most important factor in handling juvenile stealing is to determine the motive behind it and then to vary the treatment accordingly. Since an appreciation of property rights is basic to honest behavior, it is essential that the child develop this appreciation as early as possible. This may be done by giving him certain possessions for which he is to be responsible and over which he has jurisdiction, with definite places where they are to be kept. Allowances, opportunities

to earn money, or both should be provided if possible, so that the child will not be forced to resort to stealing to satisfy his wants. If stealing is used as a defense mechanism, the reasons for the child's sense of inferiority must be ascertained and he must be given legitimate opportunities to achieve success and satisfaction. Care should be taken to see that stealing always turns out to the child's disadvantage without humiliating him. Parents and teachers should recognize the problem frankly, deal with it objectively rather than emotionally, and should not remind the child constantly of his past mistakes. The child whose stealing appears to be on a neurotic basis should be referred to a psychiatrist or child guidance clinic for appropriate study and treatment. STORY TELLING. Story telling is one of the most ancient of human arts, antedating writing by thousands of years. Although much of its function has been taken over by books and more recently by the motion picture and radio, it remains useful and worthy of cultivation.

Listening to good stories is an important aid to the emotional, intellectual, and linguistic development of the young child. From it the child may acquire new ideas and vocabulary, absorb correct patterns of speech, and develop ability to pay continued attention and to follow a related sequence of events. These are important in the development of language ability and, more specifically, of readiness for reading. The telling of stories has a definite place in the activities of the nursery school, kindergarten, and primary grades.

Good technique in story telling starts with the ability to select a story suitable to the audience and the occasion, and therefore implies an understanding of children and a

good background in children's literature (*q.v.*). The preparation of a story involves complete familiarity with the events and a visualization of the situations, so that they may be vividly described in one's own words; memorization should usually be avoided. Good voice production, naturalness of expression, and the proper timing and placement of emphasis are important. A.J.H.

STREPHOSYMBOLIA. Strephosymbolia, meaning literally "twisted symbols," is a term coined by Dr. Samuel T. Orton to describe his conception of reading disability. He describes it as characterized at the outset by a marked tendency to make errors of the reversal type and by confused memory for word and letter forms. According to Orton it is caused by an absence of clear-cut dominance of one hemisphere of the brain over the other. The correctness of the theory, which has stimulated much research, is still a controversial issue. (See REVERSALS and READING DISABILITY.) A.J.H.

STUDENT ACCOUNTING—See PUPIL ACCOUNTING.

STUDENT COUNCIL. The basic idea of the student council—student participation in control—is not new; it was found in early monitorial and Jesuit schools and was endorsed by such educators as Plato, Vittorino da Feltre, Rousseau, Pestalozzi, and Froebel. Some of the early exponents used it for economy in handling large groups of pupils, but almost all of them recognized its educational possibilities.

The main purpose of the student council is to give the students—both as electors and officials—some practical training in democratic living through the setting of a miniature democracy. Through its programs of constructive activities in helping to organize, and articulate extracurricular activities (*q.v.*), the council can have considerable influence on the school as a whole.

STUDENT COURT — STUDENT LOAD

There is actually no such thing as "student self-government" in a public elementary or secondary school because students are not officially charged with the responsibility of the school; they lack the experience and judgment that must accompany legislative, executive, and judicial power; and students are minors. However, students can and should participate in control.

Successful participation rests upon the following basic principles: (1) the school must feel the need for council organization; (2) the council should be introduced and developed gradually; (3) a careful study of purposes, plans, local needs, etc., should precede any attempt at organization; (4) the school as a whole, both teachers and students, should be adequately represented; (5) every student in the school should feel his representation; (6) the council should have definite responsibilities and powers; (7) the council should be large enough to represent the entire school fairly, but small enough for efficient organization; and (8) the head of the school should retain veto power.

Representation on the council may be on the basis of (1) specialized interests—clubs, activities, etc., (2) student body generally—classes, home rooms, or at large, (3) school, alumni, and board of education, and (4) academic, citizenship, honor, or other awards, or recognition. Obviously the second plan, which represents all of the students, is more nearly democratic and is the form most commonly found. In smaller schools the representatives are usually elected from classes; in larger schools, from home rooms.

Student councils are organized internally in an almost unbelievable array of forms varying from the simplest form of single committee to the most complex imitation of national government with its legislative, executive, and judicial departments, and their many sub-divisions. Some councils imitate their state organizations while others copy the local municipal organization with its various departments. Still other forms have separate congresses or councils for each grade and a top council elected from these. And there are many other types.

To get things done the simpler organizational forms are preferable. A complicated type easily brings confusion, and effort is likely to be spent in keeping the organization

going instead of in getting things done. A simple form of council and sub-committees seems to be the most suitable for the average school. A formal installation of the council in the school assembly brings a dramatic appeal and adds to the importance and dignity of this body.

The student court, which is found in some schools, formally tries delinquent students. Administrators often doubt the value of these courts. Student courts tend to interpret misconduct as an offense to be punished and rarely as a symptom of maladjustment that needs cure instead.

A simple form of constitution which sets forth the purposes, powers, limitations, and organization of the council is necessary. It can be worked out gradually and finally be formally adopted by the school. It may then be published in a small booklet and distributed to the school. By-laws for the council itself are also necessary.

The general scope of the council's work is suggested by such activities as chartering and correlating school organizations, organizing and supervising social functions of all types, handling student employment and loan funds, and welcoming new students and visitors. (See SELF-GOVERNMENT.) H.C.M.

STUDENT COURT — See **STUDENT COUNCIL**.

STUDENT LOAD. The student load refers to the amount of work carried by the individual student during a particular term. In the American secondary school the student load is customarily defined in terms of the number of courses or subjects carried. The accrediting (*q.v.*) agencies usually specify that four unit courses, or the equivalent, shall

constitute the normal amount of work to be carried by the average pupil.

In the universities and colleges the student load is stated in terms of semester hours or quarter hours. Under a semester system a student ordinarily will carry about one-eighth of the graduation requirement. This may range from fifteen or sixteen semester hours in colleges of liberal arts to as many as eighteen or twenty in professional curricula. Under the quarter system the normal load approximates one-twelfth of the graduation requirement. (See CREDIT.) L.M.C.

STUDENT PERSONNEL WORK—See GUIDANCE

STUDENT RECRUITING. Student recruiting refers to the means used by schools, colleges, and universities to attract or to persuade students to enroll or to seek admission to their institutions. Students recruiting is a major problem of private schools, regardless of educational level or age group served, and of public colleges, normal schools or teachers' colleges, and universities, where the enrollment is not assured through compulsory attendance laws.

Since a private school or private institution of higher learning derives much of its revenue from the tuition fees paid by students, it is essential that the student body be large enough to assure enough revenue which, together with the income, if any, from other sources will be sufficient to cover the operating costs of the institution.

A public institution of higher education, while receiving some income from fees paid by its students, depends mainly on appropriations from public funds. These appropriations are usually determined by the needs of the institution as expressed through the number of students enrolled. To be assured of appropriations sufficient to finance its program, the institution therefore must have as large a student body as can be accommodated. In an institution in which the student body is not limited by a definite quota of students established by some administrative or legislative body, it sometimes becomes necessary to increase enrollment in order to secure a larger appropriation to cover the cost of some necessary or desirable change or expansion.

Private schools of all levels and types, as well as public institutions of higher learning,

through their student recruiting program, aim to persuade more students to seek admission than they will permit to enroll. The realization of this aim enables an institution to set certain requirements for admission. As the number of students seeking admission increases beyond the number that can or will be admitted, the higher or more exacting the entrance requirements can be, or the more choice the institution can have in the selection of its student body.

A program of student recruiting is in reality a public relations program directed mainly to (1) parents, relatives, and friends of prospective students, (2) the present student body, and (3) the prospective students themselves. While it is necessary that the program be effective with all three groups, regardless of the type or educational level of the institution, the older the age group served by the institution, the more effective it is to direct the recruiting program to the prospective students themselves; while the younger the age group served, the more effective it is to direct the program to the prospective students' parents, relatives and friends.

Among those activities of the public relations program of a school or college that are considered to be effective in securing students are (1) specially prepared bulletins sent to parents or to prospective students describing the curriculum, the social and recreational activities of the students, the provision for health and medical care of students, the equipment and housing facilities, and the qualifications of the instructional staff (These bulletins may be written to appeal to either the prospective student or his parents, but in either case the content is selected to appeal to the definite interests of the person for whom the bulletin is intended); (2) motion pictures of some of the activities in which the students engage; (3) personal interviews by a representative of the school or college with the prospective student or his parents; (4) "open-house" day at the school or college, to which the prospective student and his parents are invited. The program of the day is selected to appeal to both the prospective student and his parents. The public relations program of colleges also includes (1) radio broadcasts of productions of student dramatic or music groups or programs describing the various activities of the college; (2) a field

STUDENT TEACHING

representative to travel to high schools to talk to the entire student body or to confer with smaller groups, especially with members of the graduating class; (3) meetings of local alumni associations, to which prospective students are invited; (4) programs of music or dramatics by student groups sent to high schools, churches, and meetings of clubs and service organizations; (5) the activities of the sororities and fraternities designed to recruit prospective members; and (6) high school exhibitions and contests in dramatics, athletics, and music on the college campus, to which high school students are invited.

STUDENT TEACHING. *Student teaching* refers to the supervised teaching performed by prospective teachers as part of their professional training. Because the term, student teaching, conveys the idea of more than mere practice, it is often preferred to the older expression of *practice teaching*. The activities comprising student teaching range from the mere observation of an experienced teacher at work to the student's participation in both curricular and extracurricular activities. Student teachers are usually assigned to a specific class for a stated number of hours each week for a quarter, a semester, or longer, depending upon college and state certification requirements. A well-planned program of student teaching offers more than mere practice in classroom teaching. It covers the whole range of a teacher's activities, both in and out of school, and offers the student teacher first-hand experience in guiding extracurricular activities and in developing community relationships.

The student teacher usually receives help from the *critic teacher* (also called *supervisory teacher* or *master teacher*) to whose class the student is assigned, and from the supervisory instructors from the college or teacher training staff. The college supervisors are usually members of the department of education or subject matter teachers in the student's field of specialization. Where the student teaching is done in a laboratory school there is ordinarily a close relationship

between the school supervisors and the college supervisors.

Student teaching is an important part of the pre-service phase of teacher education, for it enables the student to test his understanding of educational principles by applying them to practical situations and it helps him to evaluate school practices in terms of the educational principles he has been studying. Student teaching thus provides an opportunity for integrating the prospective teacher's preparation in subject matter fields with his preparation in the foundations of education (philosophical, historical, psychological, and social).

There is no general agreement as to whether student teaching should appear early in the sequence of professional studies or whether it should be the culminating activity, not to be engaged in until the student is a senior at college or even a graduate student. Those who favor student teaching as an early experience (that is, after the student has had some, but not many, of his professional courses in teacher training), are impressed (1) by the way in which student teaching experience provides a background that gives meaning to the professional courses the student takes subsequently, (2) by its value in enabling students to see fairly early what a teacher's opportunities and responsibilities are, thus helping him to decide whether teaching is the type of career in which he will find personal and professional satisfaction, and (3) by the manner in which student teaching reveals the student's shortcomings and thus encourages an early start on remedial work. On the other hand, student teaching is also appropriate as a culminating course because (1) only a thoroughly qualified student can profit from the richness of the opportunities presented by student teaching, (2) an immature student with meagre professional background may be tempted to do little more than imitate the procedures followed by the supervisory teacher, and (3) it is unfair to school children to expose them to inadequately prepared student teachers.

The importance currently attached to student teaching has been challenged by those who believe it takes a disproportionately large share of the student's time and energy. These critics assert that the student is often plunged into a teaching situation for which he is not ready and that he flounders so badly

that both he and his pupils are hurt by the experience. Objection has been raised, also, to so narrow a conception of supervision that the student is forced merely to ape the practices followed by the supervisor or critic teacher. The value of student teaching is limited, too, when it is not brought into close relationship with the rest of the pre-service program of teacher education.

The tendency today is to lengthen the period of student teaching required for a degree, to broaden the range of teaching experiences in which the student participates, and to develop closer cooperation between the school and the college. (See *TEACHER EDUCATION*.)

STUDENTS' LOAN FUNDS—See LOAN FUNDS.

STUDY. Teaching has been defined as the guidance of learning. When the child enters a classroom the teacher usually assumes the responsibility of organizing specific learning situations in which the pupil is guided to respond most effectively. If one can judge from the frequent failure of pupils to develop efficient study habits, it would appear that many teachers either cannot teach pupils how to study, or they believe that pupils are able to develop effective methods of work without any teacher direction or guidance. Repeated investigations of the study habits of students, however, have demonstrated that there is little foundation for such a belief. Although the superior pupil occasionally may adopt fairly satisfactory techniques of study, one may be certain that only a small proportion will utilize those devices that have proved to be most effective. In fact, the pupil of superior ability whose progress is unsatisfactory may be hindered simply because he is using poor methods of study which, without adequate guidance by the teacher, will continue to stand in his way. The pupil who is below average, moreover, rarely will adopt the best available techniques without considerable

teacher assistance. It seems obvious that the classroom teacher must present to all her pupils the techniques and devices which experiment and experience have proved to be most effective, must aid her students in choosing those techniques which give the best results for them, and must inculcate the habit of using these procedures.

To assure provision for teaching pupils how to study, schools have devised a number of administrative plans. While individual schools have made variations to fit their special needs, the following plans are the most commonly used: (1) the divided-period plan, which normally consists of a long period of fifty or sixty minutes divided into two parts, usually equal in length, one for study and the other for recitation; (2) the flexible divided-period plan, which is like the first in operation except that the length of the periods is left to the teacher's discretion; (3) the flexible supervised-study period, which provides supervised study periods from day to day, whenever they are needed, as part of a larger unit of work; (4) the library or study-hall plan, which provides for supervised study under the direction of a teacher or teachers; (5) the extra-period or conference plan, which provides an extra daily period or periods during which pupils are given needed help or are supervised in their study by teachers in certain rooms; (6) the variable-period plan, which provides for using different periods on different days of the week for supervised study in all classes to teach pupils how to study, also to provide practice in studying; for example, English classes may devote Mondays to a supervised study lesson instead of to the usual classwork. language classes have their supervised study lessons on Tuesdays, etc. The variable-period plan is used in some schools as a means of reducing the students' burden of homework assignments, since the supervised study periods, sometimes called "Unprepared Day," ordinarily require no advance preparation of assignments. Some schools have provided a special course or a series of lessons to teach pupils how to study; these have been used with varying degrees of success. Since study procedures must be adapted to the type of work to be done, many educators advocate that the classroom teacher should assume the responsibility of teaching students how to study. On the other hand, if this problem is

STUDY

left entirely to the teachers, little may be done unless the school initiates a coordinated plan.

In present-day practice most schools recognize the necessity of teaching pupils how to study as a part of their regular classwork. This may be facilitated by the correct use of good assignments (*q.v.*) which grow out of the work in class, are adapted to the student's abilities, and are properly motivated. The assignment should help each student to understand not only what he is expected to accomplish but also which procedures he should employ. If the student's work is then evaluated by teacher and pupil from the point of view of adequacy of the study procedures which were used, the teacher can help the student correct many of the causes of bad study habits.

What are the most valuable study techniques? The usual procedure which is adopted in the attempt to answer this question involves the comparison of two groups of students—one consisting of students who have obtained excellent grades, and the other consisting of students whose academic success has been poor. Interview and observational data centering about the study habits of the two groups are then assembled, and the percentages of the good and poor students who utilize a particular technique are determined. Those devices that are used by a large proportion of superior students and a small proportion of inferior pupils may then be considered most valuable in promoting learning.

There is grave danger, however, in accepting the results of such investigations at their face value. It should be noted that comparisons of the type described above introduce important complicating factors—the student who obtains high grades is generally more intelligent and, in all probability, more highly motivated than the student whose academic standing is low. The study habits of the superior students, then, cannot be considered the sole casual factors operating in the situation, nor can it be said that the techniques used by superior students would be equally appropriate for the inferior student. Each student must be considered as an individual, and remedial work must be undertaken on an individual basis.

Although the improvement of study techniques is largely a matter of the guidance of the individual student, the efficiency with

which most pupils study can be improved. Some schools report that study procedures have been improved when students are familiarized with the suggestions which have been offered by educational psychologists. Typical of such suggestions are:

1. Keep in good physical condition. Students who find schoolwork difficult frequently are found to have remediable physical handicaps.
2. Make certain that external conditions of light, temperature, quiet, etc. are favorable to study. Experimental evidence indicates that such factors, if uncontrolled, lead to physical fatigue and to lowered efficiency in studying.
3. Plan your day's work in advance, and maintain the schedule which you set up. In so far as possible, study at the same time and in the same place every day.
4. Skim material to be read before you read it in detail. Such a preliminary survey will assist you in following the writer's general plan, and will make the material more meaningful.
5. Special attention should be given to diagrams, tables, and charts which appear in your reading, since they constitute the author's means of summarizing his data. Cultivate the technique of making your own charts and diagrams to summarize what you read.
6. Remember that it is worthwhile to interrupt the continuity of your reading in order to look up technical terms. Failure to do so will result in lack of understanding.
7. Provide for the recitation of what you have read. Recitation makes for better learning, and is a good way of becoming independent of the text.
8. Take notes in outline form, both on readings and classwork. Do not try to put down everything you read or hear—be selective. Use your own wording—do not try to make your notes a verbatim record.
9. Develop some method of organizing your notes so that you can easily locate materials when you want them.
10. Review your work systematically and periodically. Do not save all your reviewing for the day before examination. Cramming is a poor study technique.

Even if every one of the suggestions noted above is helpful and practicable, students will not develop good study habits merely by reading a manual in which the above points are elaborated at great length, or by participating in extended class discussion of good and poor techniques. One of the major weaknesses of most programs concerned with teaching pupils how to study is that they emphasize the student's knowledge of good study procedures rather than his habitual use of them. If the student knows how to study but is so far from being convinced of the value of correct study procedures that he lapses into his ineffective study habits when not under the teacher's direct supervision, little lasting improvement can be expected. Both the inferior and superior student will profit more from guidance in practice situations, in which problems involving study procedures are presented and worked through in the way that such procedures must be used when the pupil is studying alone. It is important that students know how to study, but it is even more important that the use of such procedures becomes habitual—and the process of habituation necessitates ample provision for practice.

The ability to study involves a number of specific abilities. Thus a person who knows how to study a mathematics assignment may not be equally efficient when studying social studies. Because so much of the student's ability to study hinges on his ability to use printed materials efficiently, the teaching of reading usually includes the development of some skills that are important in developing the ability to study. Typical of such reading skills is the student's ability in work-type reading and in the use of reference materials.

Reading, Work-Type. Reading, in which the primary aim is a practical one such as obtaining information, is usually described as *work-type reading*. Most pupils need guidance in learning to adapt their reading habits to a variety of purposes for reading and to the adjustments required by different kinds of reading material.

Specific practice in a variety of study skills is, therefore, a regular part of the elementary reading curriculum. Among the more important of these skills are (1) reading to get the central thought or main idea; (2) reading carefully so as to note and remember specific

details; (3) skimming or very rapid reading to locate the answer to a specific question; (4) reading of directions so as to be able to carry them out accurately; (5) reading and interpreting graphs, tables, charts, and maps; (6) utilization of a table of contents or index to locate information; (7) reading of dictionaries, encyclopedias, and other types of reference books; (8) reading to analyze the organization of a selection or topic and to reduce it to a summary or outline; and (9) reading critically to evaluate the author's ideas or to compare different points of view.

Developmental lessons for the improvement of the types of reading described above frequently are given in a separate period of reading instruction. Workbooks and study-type readers containing appropriate kinds of practice exercises are used in many schools. The use of textbooks in content subjects as material for lessons in reading is also widespread and commendable. (See *READING, METHODS OF TEACHING*.)

Reference Reading. The modern curriculum, with its emphasis upon the organization of subject matter in the form of problems and upon a rich program of collateral and supplementary reading, requires that reference books be available and that pupils receive training in how to use them. Basic types of reference works include dictionaries, encyclopedias, atlases, almanacs, bibliographic sources such as the *Readers' Guide to Periodical Literature*, and special book lists. Elementary reference skills that should be taught include facility in locating items that are arranged in alphabetical order, and in using an index, a table of contents, and a card catalogue.

The importance of reference reading in "elementary research" in the Activity Program (*q.v.*) and in English and the social studies on the secondary school level points to the necessity for the teacher's recognition of the many skills that must be developed if students are to gain as much as possible from their reference reading.

Typical of the skills included even in elementary research are the following:

1. Analysis of the problem or unit or segment selected by the group or individual into a series of questions or topics.
2. Construction of a "gross" bibliography

STUDY CLUBS — SUBLIMATION

of available sources (texts, magazines, reference books).

3. Location of the reference work containing a likely answer to the definite question to be followed up.

4. Resourcefulness in examining various topics listed in the index. This ability grows out of step 1 (and the lack of it spells failure on the part of most pupils in the intelligent use of the index, especially if the index is not analytical).

5. Resisting distraction by interesting but irrelevant material in the context.

6. Keeping in mind the question to be answered.

7. Evaluating the usefulness of the information given.

8. Distinguishing between facts and illustrative or immaterial anecdotes.

9. Applying the host of reading skills previously taught.

10. Taking notes intelligently.

11. Persisting until an answer to the question is found.

A similar analysis may be made of the skills involved in reference reading in secondary schools and colleges. Some of the difficulties which students at all levels experience in their independent study arise from the fact that their teachers assume that students have mastered skills which have never been analyzed or developed in class.

One of the shortcomings of most programs for improving study habits is that the problem is viewed usually as exclusively an intellectual one. Though many pupils do not study effectively because they do not know how to study, other factors may be equally important in reducing the efficiency of study procedures. Thus the student's home facilities may be inadequate for efficient study, his emotional problems may interfere seriously with his ability to study, his attitude toward school may not lead to any desire to study, and his excessive participation in extracurricular activities or the responsibilities of part-time employment may not leave him enough time for study. A complete program for improving the ability to study includes therefore a detailed study of the individual student who has difficulties in studying. J.J. and T.M.R.

STUDY CLUBS. Any group of individuals who desire to improve their grasp of a field of knowledge and who study individually and meet voluntarily at stated intervals for general discussion constitute a study club. Usually the club is composed of students in high school or college, but clubs have been formed by many groups both in or out of school to study such problems of general interest as radio, current events, contemporary literature, and science. These clubs make it possible for industrious individuals to read widely and then to pool their ideas and findings in general meetings. That attendance is voluntary gives the club members a feeling of freedom as well as affording profitable recreation and worthy use of leisure time.

SUBLIMATION. Psychoanalytically, the term *sublimation* is applied to the process of converting sexual (libidinal) drives and energy into acceptable social channels, not obviously sexual in aim. In a less limited sense it can be applied to the redirection of desires and drives which cannot be gratified in their original form without arousing conflicts in the individual. It is a protective device which is essentially sound mentally and is conducive to the promotion of satisfactory emotional adjustments. It is utilized, usually unconsciously, by the adolescent girl who, for

SUBSTITUTE TEACHER — SUPERINTENDENT OF SCHOOLS

example, becomes interested in child care or home nursing, by the boy who becomes absorbed in baseball or football, and by the adult who turns to community welfare services as part of his leisure time activity. (See **MENTAL HYGIENE.**)

G.M.A.

SUBSTITUTE TEACHER. A substitute teacher is one who takes the place of the regular teacher whenever the regular teacher is absent from school. Substitute teachers are generally selected centrally for the school system, and are approved as eligible for substitute service by the superintendent or personnel director. Most cities prescribe the same professional requirements for substitutes as for regular teachers; but at times they find it necessary to waive the requirements of experience, local residence, and marital status, in order to secure an adequate supply of substitutes.

Rating scales are used to measure candidates for substitute teaching as well as those for regular positions. The practice of permitting older pupils to act as substitutes, even for very short periods, is not sanctioned because the difficulties of substitute teaching are as great as or even greater than those of the regular staff.

Students enrolled in teacher-training institutions may gain valuable experience if permitted to do substitute work; but the practice is difficult to administer and is not used widely. Baldwin found that 38 cities out of 61 which had teacher training institutions used the trainees for substitute service. However, they did so only when the critic teacher with whom the student was studying was absent.

The selection of well-qualified substitute teachers is important in view of the facts known concerning the absence of teachers. In a study of 5,260 teachers Kuhlmann reported an average amount of absence of 5.28 days per teacher per year. Baldwin reported the median ratio of regular teachers to substitutes in certain American cities as 6 to 1 in elementary schools, 5 to 1 in junior high, and 4 to 1 in senior high schools. Cooke suggests that the number of substitutes should approximate from 10 to 15 per cent of the number of regular teachers. (See **RELIEF TEACHER.**)

SUPERINTENDENT OF SCHOOLS.

The office of superintendent of schools was established in American cities during the nineteenth century. The cities of Buffalo, New York, and Louisville, Kentucky established the office in 1837, and the city of Philadelphia, one of the last of the large cities to establish the office, created the position in 1883. Although the position has been in existence for more than a century, it was only relatively recently that it developed as an executive and administrative one.

Although the superintendency of schools as a position of educational leadership developed in American cities, it is now widely used to designate the chief officer of county school systems under the county unit plan and state school systems. While there are differences in qualifications, duties, and manner of selection of superintendents in cities, counties, and states, the office is now generally regarded as essentially an executive and administrative one. The term superintendent of schools, as applied to officers of counties functioning as intermediate units, is quite distinct from the first three types mentioned. This discussion is confined to a description of the city superintendent of schools. (See also **COUNTY SCHOOL SYSTEM** and **STATE SYSTEMS OF EDUCATION.**)

Duties and Responsibilities. The duties and responsibilities of the early superintendents often lacked clear definition. In some cases this officer acted more in the capacity of a clerk or business manager than as an executive or administrator. The development

SUPERVISED STUDY — SUPERVISION OF INSTRUCTION

of the executive and administrative aspects of the office paralleled the rapid expansion of the public education system and the increased complexity of the organization. In the typical city school system the superintendent is the executive head of both the instructional program and the business aspects. This type of organization may be described as the unitary one. In the cities of over 100,000 population about one-half had this form in 1936. In smaller cities it was more frequent.⁴ The superintendent has general charge of the educational work, selection and in-service training of teachers, the instructional program, business management, school and community relations and the supervision of certain additional educational projects such as adult education. To assist him he usually has one or more assistant superintendents with staffs sufficient to carry on the work of major departments.

Training and Certification. Special training of superintendents of schools is now generally required. In all of the large cities and in many of the smaller ones they are expected to have at least a bachelor's or master's degree, with special training in school administration. It is not at all uncommon to find superintendents in the larger cities with the doctor's degree, with major work in school administration. In 1939 the National Education Association reported that there were thirty-three states that issued special certificates in administration or supervision and in nineteen of the states such certificates were required of all local superintendents.² In addition to the qualifications of training, many states require a certain number of years of successful teaching or administrative experience in order to qualify for the superintendent's certificate.

Method of Selection. The early superintendents of schools were usually chosen from the local system and were persons who had business experience or in some cases were head teachers. Appointment to the position was often made by the city council or other governing body of the city. In recent years it has become generally recognized that the superintendent should be selected and appointed by the board of education. The selection of a local person was an early requirement which placed a restriction upon the type of person who should be secured for the office. Today this restriction has been gener-

ally removed and the board is free to select the most competent person from anywhere in the country. This method of selecting a superintendent of schools has developed through experience over a period of nearly a century.

Tenure of Office. The term of office for which the superintendent of schools is elected is generally one year. In states that have tenure laws the superintendents of schools are generally excluded from the provision of such legislation. In the absence of specific tenure legislation the general practice, especially in the large cities, is toward relatively longer terms. An initial three year term with subsequent five year terms is usually considered desirable practice.

Community Leadership. The position of superintendent of schools is now generally regarded as one of educational leadership in the community. There is a tendency toward placing him in charge of more and more of the educational activities in a community. The practice of placing all the educational activities under one executive officer of the board of education is now generally regarded as desirable.

SUPERVISED STUDY—See STUDY.

SUPERVISION OF INSTRUCTION.

The *supervision of instruction* refers to the variety of means used by administrators, supervisors, and teachers themselves to improve the teaching and learning process.

In general the trend in supervision is away from an authoritative inspection of the work of teachers by higher officials and toward a cooperative effort designed to help teachers improve their own philosophy and methods of teaching. When education was expanding rapidly in the 19th century, and when great

numbers of ill-trained teachers were pouring into the schools, superintendents, principals, and other supervisors felt called upon to check thoroughly on the teachers. Even though the profession improved its standards of preservice preparation, the line and staff (See ADMINISTRATION, SCHOOL) conception was maintained generally into the 20th century; in the last decade or two, however, newer conceptions of learning and teaching have led to newer conceptions of supervision as a means of in-service education of teachers.

Supervision was conceived formerly as the inspection by administrators of classroom management as conducted by teachers. Elaborate check lists were developed whereby administrators and supervisors rated teachers in such detailed respects as use of English and effectiveness of drill procedures, while standardized tests were given to pupils as a means of determining how well the teacher was doing his work. The supervisory officer would then tell the teacher how to improve his teaching. Thus, it was the supervisors who conducted curriculum investigations, promulgated new courses of study, selected textbooks, and prepared materials of instruction which were handed over to the teacher for use.

In recent years there has developed a more democratic and cooperative interpretation of supervision in which supervisors and teachers work together on the problems of learning. Supervisors do not intrude so often upon the actual work of the classroom but look upon themselves as consultants to be called on by the teacher when aid is needed and as leaders to stimulate self-direction on the part of teachers through cooperative study groups and individual conferences. The supervisor and the teacher work together on the individual learning and personality problems of pupils, on developing curricular materials and methods, and, in general, on the whole problem of developing an adequate philosophy of education concerning the role of the school in modern society. Supervision today considers the attitudes of teachers as a most important area of concern, and indeed often starts the process of improving instruction by focusing attention upon improving the personality of the teacher himself. The growth of this conception of supervision can be traced in part to the development of the Department of

Supervisors and Directors of Instruction of the National Education Association. Somewhat the same trends are discernible in the supervision of student teaching, where, in a sense, the critic teacher has the role of supervisor and the student teacher has the role that the regular teacher plays in the larger school situation.

This change in the purpose and the spirit of supervision has been reflected in the procedures employed. The isolated inspectional visit, during which the principal or superintendent made an unannounced visit to the classroom and either questioned the pupils himself or sat at the rear of the room observing the teacher at work as a basis for subsequent rating of the teacher's effectiveness, no longer enjoys its former acceptance as the major supervisory activity. When the supervisor visits the classroom, an increasing number of teachers have learned to regard him as a professional consultant whose training and experience should help the teacher improve his own techniques rather than as an itinerant inspector who seeks only a rating. The supervisor's visits to the classroom become a less important part of supervision as other procedures become more prominent. Thus, in many schools, the improvement of instruction is attained in other ways, such as the encouragement of inter-class visitation (*q.v.*), the enlistment of teachers' assistance in the solution of curricular problems by having teachers serve on committees which revise the curriculum and the courses of study, the use of teachers in constructing and applying rating scales to measure teaching effectiveness (See TEACHERS, RATING OF); and the inauguration of teachers workshops (*q.v.*) as means of in-service education. There is, of course, a wide range in the extent to which these changes in supervisory principles and practices have affected the many school systems in the country.

Vertical and Horizontal Organization of Supervision. An educational service is said to be administered or supervised vertically when the authority for the direction of the service throughout the length of the school system (from the kindergarten or first grade through the high school) is centralized in one agency or office. For example, business management, attendance, and health are in almost all cases organized vertically. The supervision of instruction is organized vertically

SUPERVISORY TEACHER — SUPPORT OF EDUCATION

when specialists are responsible for particular subjects throughout all grades of the system. Special supervisors of music, of art, and of physical education are representative of vertical organization.

The organization is said to be horizontal when the service is administered across the entire program of a particular vertical division. A kindergarten-primary supervisor, an elementary principal, or an assistant superintendent in charge of high schools is representative of horizontal organization for supervision and administration.

In actual practice all school systems have some elements of both vertical and horizontal organization. Emphasis on the service or subject and on specialization tends toward vertical organization, while emphasis on age and developmental level of the child, irrespective of the service rendered, tends toward horizontal organization.

Special Supervisor. A special supervisor spends his entire time in the supervision of instruction, as contrasted with the superintendent or principal who divides his time between administrative and supervisory functions. The special supervisor may be responsible for a particular division of the school (elementary supervisor, kindergarten and primary supervisor, etc.) or he may supervise the teaching of a particular subject throughout a school system (art, music, home economics, penmanship, etc.). The special supervisor is presumed to be an expert in the subject matter and methodology of either a division of the school system or a particular subject.

SUPPORT OF EDUCATION. The financial support of education in the United States varies with the methods of raising revenue in the several states and also with the type and grade of the schools maintained. Rather than one national plan of school support, there are in reality forty-eight plans of support for the public elementary and secondary schools, and a variety of patterns of support for the institutions of higher education and the special and private schools. National norms or averages give only the overall picture and do not yield much information relative to the support of education in any particular state or of a particular school.

Public elementary and secondary schools. Both from the point of view of the number of pupils served and the amount of money expended, the public elementary and secondary schools constitute the most important group of educational institutions. In all states these schools are supported jointly by the local, state and federal governments, although the proportion of support from the different governments varies greatly. According to figures reported by the United States Office of Education, the largest proportion of school revenue was received from the local governments—cities and districts—and the smallest proportion from the federal government. Table I shows the amount and percentage of school revenue derived from the various governments for public elementary and secondary schools in 1938.²

TABLE I
Income of Public Elementary and
Secondary Schools²

Source	Amount of All Revenue Receipts	Percentage of All Revenue Receipts
Federal Government	\$ 26,535,473	1.2
State Government	655,996,060	29.5
County Government	144,521,394	6.5
Local Government and Subsidies ...	1,395,831,734	62.8
Total	\$2,222,884,661	100.0

Perhaps the most striking feature of the support plans in the forty-eight states is the

SUPPORT OF EDUCATION

wide variation in the proportion derived from the different governments. Delaware had the highest proportion of state aid—92.8 per cent. Nine additional states contributed more than 50 per cent from state sources. These states were: New Mexico, 74.5; North Carolina, 70.7; West Virginia, 57.5; Washington, 56.7; Alabama, 55.5; Georgia, 53.8; Louisiana, 53.6; South Carolina, 52.4; and Florida, 52.1. Thirteen states contributed less than ten per cent of school support from state sources. These were: South Dakota, 9.7; Kansas, 8.6; Illinois, 8.4; Connecticut, 7.3; Rhode Island, 6.4; New Hampshire, 5.9; New Jersey, 4.8; Idaho, 4.6; Montana, 4.0; Iowa, 1.0; Nebraska, 0.9; Oregon, 0.2; and Colorado, 0.2.

Local governments contributed more than 90 per cent in six states as follows: Nebraska, 99.1; Iowa, 95.3; New Hampshire, 94.1; Rhode Island, 93.6; Connecticut, 92.7; and Illinois, 91.5. In only two states did the local units contribute less than ten per cent of school income. These were: North Carolina, 8.2; and Delaware, 7.2. In West Virginia the county is the smallest unit from which school revenue is derived.

In thirty-seven states the county serves as a unit from which school support is derived, the proportions varying from 0.1 per cent in Michigan to 50.1 per cent in Tennessee.²

From 1930 to 1938, state aid increased from 16.9 per cent to 29.5 per cent of school revenue receipts. This increase was accompanied by a corresponding decrease in local and county support. The former dropped from 72.7 per cent to 63.7 per cent, whereas the latter was reduced from 10.6 per cent to 6.5 per cent.²

There is today agitation for a larger proportion of federal aid than is now received by the states for public elementary and secondary schools. This necessity is based in part upon the inequalities among the states and in part upon the fact that the federal government commands more of the productive revenue sources than do the state and local governments.

Further analysis of the sources of support of public elementary and secondary schools reveal that by far the largest amount of the revenue is derived from appropriations and taxation and that a relatively small proportion comes from permanent school funds and

leases, federal aid, and other sources. Table II shows the amount and percentage of revenue receipts from these sources.²

TABLE II
Income of Public Elementary and Secondary
Schools by Sources

Source	Amount of All Revenue Receipts	Percentage of All Revenue Receipts
Permanent School Funds	\$ 20,177,226	0.9
Leases of School Lands	3,852,679	0.2
Appropriations and Taxation	2,125,780,232	95.6
Federal Aid	26,535,473	1.2
All Other Sources .	46,539,051	2.1
Total	\$2,232,884,661	100.0

Private elementary and secondary schools. Private elementary and secondary schools, of which there were 13,319, in 1938, reported a total enrollment of 2,741,654 pupils. These schools were supported almost entirely by private funds derived from tuition, gifts, subscriptions, and earnings of endowment funds. Exact figures for the income of private schools are difficult to obtain since some institutions do not make complete reports. Such figures as are reported to the United States Office of Education show that less than 3 per cent of the receipts of private schools including colleges and universities and special schools were derived from public funds. Of the income from public funds, 0.59 per cent came from federal sources, 2.27 per cent from state sources, and 0.04 per cent from county, city, and district sources. Reports show the income of private elementary and secondary schools to be \$215,852,865.³

Higher education. An analysis of the income of educational institutions of higher learning shows that the chief sources of revenue of those publicly supported are state governments, student fees, and the federal government, whereas the chief sources of support of the privately controlled ones are student fees, endowments, and private gifts and grants. The total incomes of the public and private institutions are nearly equal in amount when additions to the physical plants, auxiliary enterprises and activities, and receipts for increase of permanent funds are excluded. Table III shows the sources of income for current maintenance of public and private colleges and universities.¹

SURVEY. The survey is an organized study of the present status of an educational system, a school, or a particular problem or function involving the careful collection, analysis, and interpretation of pertinent data with constructive recommendations for future procedures. The term "survey" has been loosely used in the field of education to include studies ranging from the very specific investigation of a single school problem to such inquiries as The National Survey of Secondary Education¹⁰ and the National Survey of the Education of Teachers.⁴ While the application of this investigational method has varied widely, the method itself is relatively consistent.

Probably the best known type of school survey is that of a school system such as may be illustrated by the recent survey of the public schools of Newark, New Jersey.⁹

This survey included the study of such problems as the organization and administration of public education in Newark; the business administration of the school system; the school buildings, including a study of the condition and adequacy of existing buildings; the instructional and non-instructional personnel; the financing of the schools; early childhood education, elementary education and the education of youth in the city including the curricula, instructional materials, organization of the schools, and the status of the pupils; adult education and the recreational program; education of the exceptional pupils; guidance; and the general program of supervision and curriculum development.

Other general surveys of school systems¹ vary in scope but follow the same general procedures in that a careful analysis and interpretation of pertinent data is followed by recommendations for future policies and procedures.

Probably the next most frequent application of the survey method is the school plant survey. Such a study according to Caswell¹² should have the following characteristics:

1. Present or proposed practices or programs are questioned.

2. A comprehensive study and an evaluation are made of the status of all factors relating to the practice or program questioned.

3. Both immediate and future needs are stated as they are indicated by the status study and research findings.

4. Practices and programs are outlined to meet these needs.

The school building survey usually consists of intensive studies of such problems as

the general character and development of the community including an analysis of the population, occupations, and distribution of the people within the area; the present school enrollment according to age, schools attended, residence locations, and estimates of future enrollments; the evaluation of present buildings as to condition, present and future adequacy; the financial status of the school district including assessed valuation, bonded indebtedness, tax rate, and budget requirements; and finally, specific recommendations regarding the size, type, location, and cost of a program for the future development of the school plant in the district.

The use of the survey in the study of particular school problems has been widespread and is illustrated by surveys of teachers' salaries, pupil transportation, achievement of pupils in particular subjects, per pupil costs of education, and other specific school problems. The survey has by no means been confined to public school systems nor to the elementary and secondary school levels but has been widely used in the field of higher education. In a very thorough study of surveys of colleges and universities, Eells³ found and analyzed more than 500 written reports of such surveys.

In more recent years there has been a growing number of surveys of a social as well as an educational nature. The broader concept of the program of the schools has created a need for studies of community recreation facilities; pupil health; employment; leisure time activities; traffic accidents; economic and educational status of children and of adults; and general social surveys of entire communities such as that which the Lynds made of "Middletown",⁷ and of correctional institutions such as the Boys' Industrial School in Ohio.⁵

The more comprehensive surveys have generally been made by a staff of experts from outside the particular school or school system. While this procedure is still the prevailing practice, there are, however, a growing number of schools which are maintaining within their own organizations a research staff to conduct studies of numerous phases of the school program.⁸ These research bureaus devote a considerable proportion of their time to studies of the survey type and frequently carry on "continuous surveys."

While research bureaus and staffs of experts represent the better publicized method of conducting surveys, the survey method is widely used by individuals. A large proportion of the theses of candidates for degrees are surveys.

It is difficult to appraise the survey in terms of its fundamental value or of the contribution made to the general development of education through its use. That there have been poor surveys as well as good surveys cannot be questioned. That school surveys have had a valuable influence is also unquestioned. Criticisms, many of which were well founded, have been made of survey methods. In the earlier surveys, the opinions and judgments of the surveyors were based largely upon subjective observations and frequently reflected the bias or prejudice of the individual. The gradual refinement of survey technics and particularly the development of more scientific means of measurement in education have done much to eliminate this weakness. Some of the comprehensive surveys have been faulty in that they have been somewhat superficial and have resulted in conclusions and recommendations which were not sufficiently specific to be of much value. In some cases the inability of outsiders properly to sense and evaluate peculiar local conditions and problems has also resulted in justified criticism.

These and other objections, while valid in many instances, are balanced by obvious and unquestionable values which have come to the science of education through the school survey. Charles H. Judd⁶ has summarized this view as follows:

"The survey movement . . . has proved to be highly important, not only because of the information that surveys have supplied to communities and school officers, but also because of the opportunity they have given to students of the science of education to develop techniques of investigation. There can be no doubt that the rapid progress made by the science of education between the years 1910 to 1920 was in no small measure due to the extensive use in school surveys of measurement techniques and techniques of comparison."

The survey as used in education is a method of investigation which, like other methods, has a valuable function when properly used. Its function is not to explore new and untried

paths nor to do what scientific experimentation alone can do, but it does supply the best means now available to collect, analyze, and interpret data regarding present school conditions or affecting some particular phase of education activity. (See also COMMONWEALTH TEACHER TRAINING STUDY; EIGHT YEAR STUDY; NATIONAL SURVEY OF TEACHER EDUCATION; SECONDARY SCHOOL STANDARDS, CO-OPERATIVE STUDY OF.) W.E.A.

SURVEY COURSES. Survey courses are those which are organized for the purpose of giving pupils a broad view of a particular area or subject. Such courses have been organized in practically every subject field and are most popular at the high school and college levels. A survey course in American Life attempts to give the student a broad understanding of problems of American life and utilizes subject matter in the fields of history, sociology, economics, and political science.

Likewise, survey courses in science take their content from the fields of biology, chemistry, astronomy, and physics. Such courses in literature attempt to give a broad general outline of the period or subject studied. As a part of the junior college movement much attention has been given to survey and background courses in both the social and physical sciences. Experimental programs have been developed at such institutions as Stevens College, the General College of the University of Minnesota, and Columbia University. At the high school level the most generally used survey course is in the field of social studies.

The introduction of survey courses has been defended as a means of counteracting the excessive specialization and departmentalization (*q.v.*) of the high school and college curriculum. Organized in terms of broad areas they tend to focus the students' attention on basic principles rather than on detailed factual material. Moreover, they make it possible to give at least an introduction to the major areas of human knowledge to all students, even though some of these students could not include in their programs of study separate courses in each of the subjects included in the survey course. Since survey courses stress the interrelationship of the various subjects included, justification has been claimed for the inclusion of survey courses even in the programs of those students who will later specialize in one of the subjects in that area. Other proponents of the survey course see in it a means of re-educating teachers to a continued understanding of the interrelationships between their subject and other subject matter areas.

Survey courses have been opposed, and in some instances have been discontinued after having been introduced, by those who see in this type of course an invitation to superficiality. These critics maintain that a subject has to be studied intensively to be understood and they see little value in the smattering which many students get as their only gain from having taken such a course. Mention has been made of the difficulty of finding teachers whose background is sufficiently broad to teach a survey course effectively. Objection has been raised, too, to the organization of many survey courses which, despite their professed interest in basic understandings, nevertheless organize the survey in terms

SURVEY TESTS — SWEDEN, EDUCATION IN

of unrelated, condensed versions of traditional courses.

Those who have taught survey courses often agree that the plan has much to commend it, but that the conduct of these courses frequently fails to solve satisfactorily many of the educational problems involved in the organization of the curriculum, and in the guidance of teaching and learning activities.

SURVEY TESTS — See **ACHIEVEMENT TESTS; STANDARDIZED TESTS.**

SWEDEN, EDUCATION IN. The Swedish system of education is comprehensive and efficient. It has resulted in a fundamentally civilized nation with practically no illiteracy.

Secular education began after the Reformation with Gustaf II Adolf; it declined in the war-torn 17th century, but rose again during the 18th as one compensation for lost political power. Advanced and elementary education developed further in the 19th century. In 1842 the first law providing national elementary schooling was passed, and the first state seminary for teachers was founded. Henceforth the state became the decisive factor, replacing private initiative and church influence. The 20th century brought school reform laws (1905, 1918-19, 1928, 1935-36) and the enforcement of compulsory education.

The highest school authority under the government is the *Ministry of Public Worship and Education*. A *Board of Education* controls elementary and high schools and teacher-training institutions.

Elementary education consists of a two-year school for small children (*småskola*) and the elementary school proper (*folkskola*), lasting four to six years. School age begins at seven, and by 1948 attendance will be compulsory till the age of fourteen (law of 1936). The statutory school year (Sept. 1st to June 1st) lasts 34½ weeks. Until recently, many elementary schools ran half-time because of severe winters and the use of child labor. These half-time schools are gradually disappearing; in 1935, only 6.6% of all school children attended them. Traveling schools in Norrland and Lapland facilitate rural instruction, as do communal homes and workshops for children, school busses, etc.

After graduation from elementary school

all students not elsewhere enrolled must attend continuation school (*fortsättnings-skola*) for one or two years. If their performance here is unsatisfactory, they must continue until the age of eighteen (360-540 hours). The bi-weekly classes offer general civic education and professional training.

Elementary and continuation schools are free. They are financed by the municipalities (grounds, buildings, repairs) and the state (administration, supervision, teachers' salaries).

Teachers are trained in seminaries connected with practice schools. Only women teach in *småskola*, but both men and women teach in the elementary school proper.

With the belated but rapid industrialization of Sweden, state and municipalities have provided opportunities for post-elementary education in Intermediate Communal Schools, Higher Elementary, Apprentice, Trade, and Household Schools, etc.

Secondary education, reaching about 50,000 students, is mainly represented by two types of schools: (1) Lower secondary school (*realskola*), 6 years, following 4 years of elementary school; (2) Higher secondary school (*läroverk*), consisting of lower school (*realskola*), 5 years, and upper school (*gymnasium*), 4 years (*ringar*). The *gymnasium* has two divisions: the classical branch (*klassiska linje*) and the scientific and modern language branch (*reallinje*). The *realskola* corresponds approximately to an American high school. The curriculum, however, is more exacting and allows no individual differentiations. In the *gymnasium* the students may choose one of the divisions, and there is also some flexibility in the last two "rings." On completion of the *gymnasium*, students may enroll in any university.

A third type of secondary school, the *Lyceum*, was introduced in 1927. It is based on six years of elementary school and provides six years of general liberal education, stressing Swedish and civics.

Secondary schools have low tuition fees, 100-120 *kronor* a year (about \$27-\$33) and numerous scholarships.

All secondary schools require entrance examinations and comprehensive, written and oral, final examinations (*realexamen* for *realskola* and *lyceum*, *studentexamen* for *gymnasium*).

SWEDEN, EDUCATION IN

Private day schools and boarding schools are few and not important, except as experiments in progressive education.

Up to 1904, public higher education was for boys only. The one state school for girls (*Statens normalskola för flickor*) was a practice school for the State Higher Training College for Women Teachers. Private girls' schools required four or six years of elementary school and lasted seven or five years respectively, with no examinations. After 1905, a number of public high schools for girls were founded. Since 1927, all secondary schools must admit girls unless equivalent public girls' schools are available. Thus today most high schools are coeducational.

High-school teachers (*lektor, adjunkt, magister*) are trained chiefly at universities; they must take a State Examination in addition to academic degrees.

The methods of instruction in all schools, based mainly on memorizing from textbooks and on discipline until 1905, have since been modernized. Ideas came partly from Swedish (Ellen Key, Emilia Fogelklou, and others), partly from American educators (W. James, J. Dewey), partly from German school reforms after 1918. A series of government regulations, prompted and backed by liberal and labor groups, provided for adaptation of instruction to individual abilities and needs; elective courses; unification of the school system; integration of subjects; personality development; activization of studies; student self-government; school libraries; physical and manual training; and development of social consciousness.

Sweden has made two contributions to international education: work (1) in arts and crafts, or *sloyd*, and (2) in gymnastics. *Sloyd* is compulsory in elementary and intermediate schools, elective in secondary schools; its part in Swedish life goes beyond these schools. Swedish gymnastics, first organized by Per Henrik Ling in 1813, is practised in all schools and has been adopted in other countries. Like *sloyd*, it aims rather at well-rounded development of student personality than at spectacular achievement.

In medical care Sweden is a pioneer. Elementary schools received regular medical supervision in 1830, secondary schools in 1868. Today all schools have free medical, dental, and hygienic care.

There are schools for the blind, deaf-and-dumb, feeble-minded, and the delinquent; these schools are as yet not sufficient for existing needs.

Nursery schools and kindergartens exist chiefly in cities, in connection with cooperative or municipal housing projects. Though private, they are often subsidized by communities or sponsoring organizations.

Sweden's universities are the two old state universities of Uppsala (1477) and Lund (1648); the State Caroline Medical Institute of Stockholm (1805); the private universities of Stockholm (1877) and Gotenburg (1898), today largely municipally supported. Any student of a Swedish or American university may take degrees: *kandidat* (after 4 years); *filosofie magister* (5 years); *licentiat*; *doctor*. Scholarships and student self-help are less frequent than student loans, which burden many students for years. There are modern research institutes, mostly in science and medicine, and research libraries; also museums of Fine Arts, history, and ethnology.

Widespread voluntary adult education is one of the chief elements of Sweden's democratic way of life. The exact number of persons participating cannot be computed, but after a slight decrease since 1935 it still amounts to about one-half of the population. Public libraries have increased and developed since the first large state grant in 1907. In 1938, 8,200 libraries lent 15,488,000 books to 1,400,000 borrowers—one-fifth of the nation. People's High Schools (*folkhögskola*), introduced from Denmark (See FOLK SCHOOLS) have grown independently since 1868. They open new fields of knowledge, chiefly to the working classes, through an important experiment in cooperative living. Today there are 60 of them, mostly rural, specializing in various fields of interest (religion, workers' education, cooperative economy, etc.). Lecture courses are arranged by lecture societies, mostly state subsidized and supervised. An original Swedish creation is the study circle, originating in the temperance and labor movements. In 1940, 1200 such circles, studying various topics, held 388,000 meetings. The Workers Educational Association (ABF) and the Cooperative Associations (KF) sponsor the largest number, but all courses are politically non-partisan. They

SWITZERLAND, EDUCATION IN

are supplemented by special journals, radio service, and correspondence courses (28,000 in 1939).

Statistics. (All figures, unless otherwise stated, are for the year 1940 or a median

of the years 1938-40, as given in the official Statistical Yearbook for the years 1941 and 1942.)

Total population of Sweden: 5,371,000.
Children between 7 and 14 years: 761,287.

SWITZERLAND, EDUCATION IN.

Organization. In Switzerland education is the function of the twenty-five cantons and semi-cantons. In each, education is under the control of a Department of Education

which exercises administrative and supervisory duties.

This division of powers of education reflects the historical development of the country from the first union of three mountain cantons in 1291 down through the Napoleonic period when Geneva was admitted to the *Confederation Helvétique*. As each addition was made to the country's territory, local control over education was continued with the final result that the Federal government possesses such powers as were given in the constitution of 1874 or granted through legislation at other times.

The 1874 constitutional provision affecting education demands that the cantons establish and maintain a system of free elementary education, that attendance be required in these free elementary schools, and that religious freedom be protected. Subsequent legislation has allowed for federal aid which is generally based on (1) total popu-

lation within the canton and (2) the difficulty of maintaining schools in remote mountainous districts. The amount of subsidy is approximately twenty cents per capita within the canton and thirty-five cents per capita in remote mountainous districts. The schools are supported, in addition to the federal aid, by special cantonal and municipal school funds and taxes. The Federal government operates but one institution, the Federal Polytechnic School in Zurich (founded in 1854). The Federal government has passed legislation dealing with compulsory physical education and with stipulations concerning the employment of youth.

Cantonal Organization and Administration of Education. Each canton has established a system of elementary education, most of them administer programs of secondary education, and several operate universities or other institutions of higher studies. Private schools—elementary, secondary, and higher—may exist but all are subject to cantonal inspection and supervision.

A number of pre-school institutions exist, among which are infant schools (chiefly for children of working mothers), Froebelian kindergartens (chiefly in German Switzerland), and nursery schools and Montessori (see MONTESSORI) schools (chiefly in French and Italian Switzerland). These schools are both public and private, free for necessitous parents and sometimes free for all.

Elementary education provides variously for ages six to sixteen. In some cantons an elementary school of four years is followed by a so-called secondary school of four years. Elementary schools extend over four to eight years and secondary schools over two to four years. These secondary schools are in reality complementary to the regular elementary schools. The subjects studied in the elementary schools usually include one national language in addition to the vernacular. Practical subjects, such as household management and shop work, are introduced before the close of the elementary period. Teachers are trained in the seventeen normal schools or the twenty-five special institutes or departments attached to other institutions. Teachers are selected by the school committee assisted by the popular vote of the parents.

Continuation schools offer courses of a

general cultural nature, in household arts, and in agriculture, for part-time students who have completed the elementary school. Various kinds of vocational schools, commercial, trade, and agricultural, are found. These have prospered partly because of federal subsidies and a federal law that requires the vocational training of apprentices to be conducted, wherever possible, in the schools.

Swiss secondary education, as the term would be used in the United States, is administered in *gymnasiums* (boys) and *lyceums* (girls) in the German-speaking area; in *collèges* (boys) and secondary schools (girls) in French-speaking Switzerland; and in schools under other names. These schools prepare for the universities and for the Federal Polytechnic School. The curricula are classical, scientific, and modern (languages). The courses vary in length from five to nine years. Entrance into the professions is in the hands of the Federal government, which specifies the educational requirements, in both the secondary school and the university. The completion of the secondary school is marked with the passing of a Federal examination which admits students to the university, provided the subjects passed are prerequisite to the university course for which the student matriculates.

In some cases the cantons operate the secondary schools; in others, the municipalities. Small fees are added to cantonal and municipal taxes and to Federal subsidies for the support of these schools.

The teachers are highly trained university men and women; frequently they conduct classes in the university as well. They are at the same time expected to have a broad general education and competence in their subject specialties.

Higher institutions are of three kinds: the universities, of which there are seven, located at Zurich, Berne, Fribourg, Bâle, Lausanne, Neuenburg, and Geneva; the Federal Polytechnic School at Zurich; and certain others organized for specific purposes, e.g., the Jean-Jacques Rousseau Institut and the Graduate Institute of International Studies in Geneva, and advanced conservatories and art schools in various cities. The Rousseau Institut is devoted to advanced study of educational problems and is the only institution of its kind on the continent; the Graduate

Institute (temporarily operated in other countries during World War II) specializes in the field of international relations. Both institutes grant doctorates through the University of Geneva.

Important influences on education have emanated from Switzerland. John Calvin published his *Institutes of Christianity* in Geneva in 1536, founded the *collège* there in 1559, reorganized the faculties into the University of Geneva, and established the union of state, school, and church which served as the basis for the New England tradition in American education. Rousseau (*q.v.*), author of *Émile*, was born in Geneva in 1712; Voltaire's home for years was just outside the gates of Geneva across the border in France. Pestalozzi (*q.v.*) operated his schools in Burgdorf, Stanz, Yverdon, and other Swiss towns. Fellenberg developed the manual training idea and agricultural education at Hofwyl. Herman Krüsi came over from Switzerland to work with E. A. Sheldon at the Oswego Normal School. Louis Agassiz emigrated from his Swiss home to become one of the outstanding teachers in American higher education. Among the outstanding educational leaders of modern times the following deserve mention: Pierre Bovet, J. L. Claparède (*q.v.*), and Jean Piaget (*q.v.*) at the Rousseau Institut; William E. Rappard of the Graduate Institute in Geneva; and C. G. Jung, world famous psychoanalyst, at the Federal Polytechnic School in Zurich.

TEACHER EDUCATION. Teacher education refers to the whole range of activities that constitute preparation for, and improvement of members of, the teaching profession. It includes pre-service education for those who have not had teaching experience and in-service education for those who are actually engaged in teaching. The elevation of quantitative and qualitative standards for the profession is reflected in the use of the term "teacher education" rather than the older term "teacher training." Whereas teacher training suggests the development of a rather narrow proficiency in the skills or methods of classroom teaching, teacher education connotes the broad professional preparation needed for the highly complex task of teaching in the modern world.

The formulations of the aims of teacher education are many, but in most of them will be found some recognition of the following objectives: (1) Since the personality of teachers has so great an effect upon students, it is most important that teacher education aid prospective teachers to achieve balance of personality. (2) Prospective teachers should gain a rich first-hand experience and broad understanding of our culture, in order to enhance the cultural experience and understanding of their students. (3) If the schools are to be an agency for the preservation and improvement of our democratic society, teachers should not only study the social, political, and economic bases of democracy but should also have experience in working, studying, and living democratically while preparing for teaching. (4) Prospective teachers should gain an adequate understanding of the process of human development, growth, and learning at all age levels and become competent in guiding the process of growth and learning of young people both in and out of school. (5) Prospective teachers should gain an un-

derstanding of the resources and methods of critical inquiry in the organized fields of human knowledge that are appropriate to their work as teachers, in order to help young people to use similar resources and methods in solving their own problems. (6) Teachers should develop a working philosophy of life and of education appropriate to their professional function and to the democratic society in which they are to function.

Within such a framework the pre-service education of prospective teachers has expanded its purposes and raised its standards in many ways. Replacing the older conception of "training" as embodied in the earlier normal schools (*q.v.*), new institutions of teacher education have appeared in the last fifty years. Teachers colleges (*q.v.*), departments of education within liberal arts colleges, and schools or colleges of education within universities have become the dominant professional institutions of teacher education. Secondary school teachers commonly receive their pre-service education in liberal arts colleges (*q.v.*), teachers colleges, and universities; elementary school teachers are prepared principally by teachers colleges, normal schools, and universities.

The trend in recent years has been to extend the number of years of professional preparation as well as to raise the quality of such preparation. Whereas the normal school of the nineteenth century required only an elementary schooling or two years of high school before the one or two years of professional training, the usual requirement today is high-school graduation before admission to the professional institution and a bachelor's degree before beginning to teach. Some states are requiring new teachers to obtain the master's degree before they begin to teach in the high school.

The pre-service education of teachers is coming to be recognized as including the following four elements: general academic background, subject matter specialization, foundations of education, and induction into teach-

ing. The general academic background is intended to give the prospective teacher a broad acquaintance with the major areas of organized knowledge and of human activities. This may be emphasized in the first two years of college or may continue throughout the pre-service period.

Subject matter specialization in the field in which the prospective teacher will work is usually required as a special competence in addition to the general education. The trend has been definitely to widen the conception of what a field of specialization is, for example, to urge specialization in the general field of science rather than merely chemistry or physics or botany or zoology. This "broad field" approach is intended to achieve an integration of the related subject matter fields and usually applies to such classifications as the humanities and language arts, social sciences, science and mathematics, and the arts. (See INTEGRATION.) The methods of teaching the subject matter fields are sometimes taught in connection with the "academic" subjects but more commonly in "methods courses in education.

The foundations of education or "courses in education" are usually intended to give the prospective teacher a wide acquaintance with the field of education in its various relationships and to provide a common background of professional outlook and acquaintance with educational problems that are common to all teachers no matter what subject they may teach. The foundations function is usually achieved through courses in philosophy or principles of education, history of education, educational psychology, and educational sociology or the social relationships of education. Some institutions are attempting to weave the elements of these separate foundational approaches into an integrated orientation to the whole field of education.

The induction into teaching is intended to give the prospective teachers the opportunity to apply in actual teaching situations the theoretical principles of education and the subject-matter knowledge that they have acquired in their general education, their subject matter specialization, and their foundations of education. Induction thus is coming to be looked upon as a continuing process that includes observation of instruction and participation in teaching procedures, and

culminates in actual student teaching (*q.v.*) or practice teaching.

In addition to the improvement in pre-service education, a desire to stimulate and continue the professional growth of teachers has led to a vast increase in the opportunities for the in-service education of teachers in the last fifty years. The more common means of in-service education include supervision of instruction (*q.v.*); inter-class visitation (*q.v.*) and visits to schools that are similar to the teacher's own school or reveal contrasts; consultative services made available to the teacher either by regular members of the local school system or by visiting consultants; summer, extension, or part-time study at a higher institution; research work, survey work, and writing and speaking on professional topics; and participation in workshops (See TEACHERS' WORKSHOP), teachers' meetings (*q.v.*), professional organizations, and community work. In general, the conception of in-service education has changed from an authoritative control over teachers' activities to a cooperative improvement of all of the teachers' functions.

Summer study at higher institutions has become one of the most popular and important of the direct methods of professional growth for in-service teachers. Most institutions of teacher education make special provisions for summer sessions and for part-time study in which teachers can engage while carrying on their jobs, either by attendance in late afternoon or evening hours at a nearby institution or by extension and home study work. Many institutions provide extra-mural courses in off the campus centers easily accessible to teachers. Through such methods teachers can broaden their professional background or can carry on advanced work in their field of specialization leading to research and higher degrees. One of the most important developments of in-service education in recent years is the workshop movement. Intended to improve upon traditional practices and those of teachers' institutes where teachers gather for two or three days to listen to speeches in large or small groups, the workshop tries to increase the participation of teachers in their professional growth by centering attention upon the individual problems that a teacher faces in his or her own professional situation.

TEACHER EDUCATION, COMMISSION ON

In addition to these methods the various kinds of professional organizations provide direct means of in-service growth for teachers. The National Education Association (q.v.) is the largest educational organization in America and includes numerous affiliated associations of a specialized kind and many state and local teachers' associations. The American Federation of Teachers (See TEACHERS' UNION) and the Progressive Education Association are smaller but influential national organizations of teachers who find considerable professional stimulation from their work in these groups. There are also numerous national organizations of teachers devoted to one or more of the recognized subject matter fields. Finally, hundreds of local teachers' associations enroll many teachers and carry on their own professional programs. Somewhat more indirect and less formal in its achievement of professional growth but none the less important is the stimulation provided by professional and general reading, travel, sabbatical leaves, and community work of all kinds. The struggles to achieve better salaries, regular increments of salary, health and sick leaves, and retirement and tenure status all help to create the conditions of work necessary for the development of the attitudes that lead to professional growth.

Outstanding in the uplifting of the education of teachers has been the great amount of research and investigation on a wide range of professional problems that has been carried on in the past fifty years. Foremost among these investigations has been the work of professional educators at teachers colleges and schools of education throughout the country, as well as the work of such professional organizations as the National Education Association, the Progressive Education Association, the National Society for the Study of Education (q.v.), the National Society of College Teachers of Education, the American Association of Teachers Colleges, the John Dewey Society, and many others. Such surveys as the *Commonwealth Teacher-Training Study* (q.v.); the study by Learned, Bagley, and others (See bibliography); and the *National Survey of the Education of Teachers* (q.v.) have also had a great deal of effect. A somewhat different approach to the improvement of teacher education is represented by the Commission on Teacher

Education of the American Council on Education (q.v.). Through the work of the Commission since 1939, many liberal arts colleges, teachers colleges, universities, and school systems have been stimulated to engage cooperatively in improving and evaluating their programs of teacher education. R.F.B.

TEACHER EDUCATION, COMMISSION ON (American Council on Education). Early in 1938 the American Council on Education established the Commission on Teacher Education to serve for a period of five years. Two years previously, the Problems and Plan Committee of the Council had interested itself in studying the problems of teacher education. One part of its report dealt with the creation of a Commission to make a nation-wide study concerning the problems facing the institutions of higher learning relating to the training of

teachers. A total of \$250,000 was secured from the General Education Board to further a thorough and intensive study.

The Commission on Teacher Education has worked in close cooperation with existing agencies that are concerned with the education of teachers and has drawn on independent study and research conducted by colleges and universities. Twenty colleges, universities, and teacher training institutions, and fourteen public school systems were selected as cooperating agencies. A number of conferences have been held at several universities and the Commission has printed reports from time to time concerning the progress of the study.

In dealing with the problem of teacher education the teacher has been thought of as a "complete human being". The Commission has been concerned with teacher education from the time teachers enter service to the time they withdraw from it. The Commission's study has been devoted, not only to "preservice" training but also to "inservice" training. In addition to these broad fields the Commission has been interested in the determination of objectives; the recruitment, selection, and guidance of teachers; the development of adequate understanding of the nature of the child; the development of social understanding and of skill in cooperating educationally with community agencies beyond the school; and the development of creative powers in teachers. The main emphasis of the Commission has been in the field of child development and in teacher selection and adjustment. Recently it has been devoting much of its attention to the problem of the teachers' part and responsibility in a democracy and a changing social order. Recent conferences and reports have emphasized that education cannot exist in a vacuum—it cannot remain aloof from society, but as a part of the general culture must take a part in shaping the future. TEACHER EXAMINATIONS, NATIONAL. The national teacher examinations, administered for the first time in March, 1940, to 3,726 candidates and again in March 1941, to 4,718 candidates for teaching positions throughout the country, consist of a set of common examinations covering the specific fields in which the candidate expects to teach. It is planned to administer these examinations annually. The common examinations consist of sections designed to test reasoning (40 minutes); English comprehension (40 minutes); English expression (40 minutes); general culture, which includes current social problems, history, and social studies, literature, science, fine arts, and mathematics (180 minutes); professional information, which includes education and social policy, child development and educational psychology, guidance and individual and group analysis, general principles and methods of teaching (120 minutes); and contemporary affairs (60 minutes). It is obvious, therefore, that these examinations are essentially tests of knowledge rather than of attitudes and skills. They are recommended on the theory that admission to the teaching profession in any capacity should be restricted to those teachers who possess more than a certain minimum of professional preparation, culture, and intelligence. The optional examinations, of which

candidates for elementary-school positions take the first and candidates for the secondary level any other two, are designed to show the mastery of subject matter; they are: 1. Education in the Elementary School; 2. English Language and Literature; 3. Social Studies; 4. Mathematics; 5. Biological Sciences; 6. Physical Sciences; 7. French; 8. German; 9. Spanish; and 10. Latin.

All examinations are of the objective type and consist of multiple-choice, short-answer items. Teachers of extended experience and graduating seniors in teacher-education institutions do equally well with them.

These National Teacher Examinations were developed under the direction of the National Committee on Teacher Examinations which was appointed by the American Council on Education. This committee was authorized to supervise and delegate to the Cooperative Test Service the task of preparing them and examining the teaching candidates. The committee was enabled to undertake this project by a subvention from the Carnegie Foundation for the Advancement of teaching.

These annual examinations make possible for the first time a direct comparison of candidates from widely scattered sections, on certain abilities thought to be associated with teaching success. However, there has been some controversy concerning the desirability of selecting teachers on the basis of scores made by candidates on widely standardized objective tests. The National Committee on Teacher Examinations has therefore repeatedly emphasized that the examination results should not be used as the sole basis for teacher selection.

TEACHER FAILURE. Types of personalities who fail as teachers, and the causes of teacher failure are not known with any great accuracy. The difficulties encountered by beginning teachers have been studied and methods of guidance have been suggested for them. But the teacher who fails and drops the work disappears from notice.

Among the chief causes for the failure of teachers appear to be (1) a lack of real interest in the purposes of the profession; (2) a lack of aptitude for it; (3) specific irritations or frustrations which may destroy initiative; and (4) clashes with administrative procedures. Some frustrations may arise from (a) too much work, (b) unfair criticism, (c) lack of opportunity to talk over problems with supervisory officers, and (d) dissatisfaction with policies of assignment of work or salary.

Many of these difficulties can be precluded or overcome through (1) more realistic teacher training; (2) improved pupil-teacher and internship plans; (3) better selection of students by teachers' colleges; (4) a more careful selection of teachers by superintendents and school boards; (5) gradation in assignments of extra responsibilities; and (6) helpful and sympathetic supervision.

TEACHER LOAD. *Teacher load* and *service load* are synonymous. Distinction should be made, however, between *service load* and *teaching load*. Superintendents should discriminate between the two and point out the difference to applicants who should recognize that their service load will be one thing, and their teaching load will be another. In brief, all teachers are expected to carry many obligations beyond those directly related to meeting their classes.

Class work, preparation for classes, tests, examinations, recitations, attendance at or work with assemblies, committee work, departmental meetings, faculty meetings, requisitions and reports, lesson plans, notebooks, correction of papers, and other activities relating directly or indirectly to the task of teaching make up the *teaching load*. The sum total of all activities involved in the teaching load plus all the other duties incident to teaching, such as extracurricular duties and community duties, constitute the *service load* of

the teacher.¹ The teacher load is affected by such factors as the length of the class period, the total number of pupils taught, the number of sections into which they are divided, the individual differences and other personality traits of the students, the nature of the subject taught, the time necessary for preparation, the number of different preparations necessary, and the amount of time given to co-operative activities.

Many in the field have attempted to give these matters consideration by setting up measures for determining the load a teacher is carrying. Among the formulas is one used by Douglass which takes into account units of teaching load per week (TL); class periods spent in classroom per week (CP); number of class periods spent per week in classroom, teaching classes for which the preparation is very similar to that for some section, not including the original section (Dup.); number of pupils in classes per week (NP); number of class periods spent per week in supervising the study hall and student activities, attending teachers' meetings, doing committee work, assisting in administrative or supervisory work, participating in other co-operative activities (PC); and the gross length in minutes of class periods (PL).

$$TL = \left[CP - \frac{2 \text{ Dup}}{10} + \frac{(NP - 20 \text{ CP})}{100} + \frac{PC}{2} \right] \left[\frac{PL + 55}{100} \right]$$

In studying 1,263 secondary-school teachers and principals in Minnesota, Quanbeck and Douglass, using the Douglass formula, concluded that high-school teachers in small schools have heavier teaching loads than do such teachers in large schools; teachers in accredited institutions have greater loads than those in the non-accredited institutions; beginning teachers have heavier loads than those who have taught for long periods; and teachers of physical education, home economics, industrial arts, and foreign language carry lighter loads than other teachers.³

TEACHER-MADE TEST—See STANDARDIZED TEST.

TEACHER PARTICIPATION IN ADMINISTRATION — See ADMINISTRATION, SCHOOL.

TEACHER PLACEMENT. The American Association for the Supply of Teachers was organized in Philadelphia in 1835. It operated more as a teachers' organization than as a placement office. In 1846, a commercial teachers' agency was opened in Boston. Between 150 and 200 commercial teachers' agencies operated in the United States in the 1880's, with educational institutions recognizing meager responsibility for teacher placement until almost the close of the nineteenth century. Today, most teachers are placed by one or more of the following agencies: college and university placement bureaus, commercial teachers' agencies, governmental employment agencies, state and national educational associations, and the teacher recruiting agencies of city and state school systems.

Superintendents do not agree in their preference for college placement bureaus, private teachers' agencies, or governmental placement agencies. Those who prefer college and university placement bureaus cite two major advantages for this kind of solution to the vexing problems of teacher placement. Since these bureaus usually function as an institutional service to graduates, they escape the commercialism of the private agency which receives five per cent or more of the salary for the first year. Moreover, the college bureau is often more frank concerning the candidates' qualifications, although reputable commercial agencies are also very conscientious in selecting and recommending their candidates.

Twelve state departments of education maintain placement services for teachers and three others conduct some placement informally and incidentally. In five additional states, the state educational associations maintain teacher placement services. Eleven states have incorporated this type of service with their regular public employment service. The service they give is free to both employers and applicants. Thus, thirty-one states have provided for some type of state-wide placement service for teachers.

To facilitate the work of placement offices, whether they operate state, institutional or private agencies, school administrators should submit full descriptions of the positions for which teachers are desired. The administrator should furnish the placement bureau with an occasional evaluation of the work of the teacher placed by the bureau. Cooperation between superintendents and teacher-placement officials will result in more effective teacher-placement. Teacher-placement will be improved when teachers who seek positions give references to school people rather than to their personal friends, ministers, and political office holders.

TEACHER-PUPIL RATIO—See PUPIL-TEACHER RATIO.

TEACHER RECRUITING. Recruiting the best candidates for teaching service is done in a variety of ways. The principal and teachers in the local high school may help young people to decide upon or against teaching as a vocation. Communities may help to establish standards for the teaching profession. Colleges and universities are largely responsible for selecting candidates for admission to their teacher-education courses, and may provide guidance to prospective teachers.

Prospective teachers, while they are attending high schools or the earlier years of the university, should be guided into subject fields that are increasing in popularity or holding their place, rather than into those that are disappearing from the curriculum. Thus, Overn showed that certain fields were disappearing from the program of studies in Minnesota high schools during a ten-year period, while other fields were being taught by rapidly increasing numbers of teachers.

Superintendents seek those immediately ready to accept positions (1) by means of published announcements of vacancies and the

use of voluntary applications, (2) by asking for the names of recent graduates from teacher-training institutions, and (3) by soliciting the services of state employment agencies or commercial teachers' agencies.

Interviewing a prospective teacher is a task for the superintendent, principal, assistant superintendent, or a committee. All interviewers should be trained specifically for the work of interviewing, and should use carefully prepared forms to record their ratings. A typical form may provide for marking on a five-point scale such things as the personality, speech, dress, physical characteristics, educational philosophy, and professional outlook of the teacher. Other qualities considered in relation to teaching efficiency are intelligence, scholarship, and adaptability.

Some examiners believe that it is better to have an orderly review of all factors examined, with a definite weighting for each, than to risk the greater injustice of failing to consider all the qualifications. There is a tendency toward the use of objective devices for rating new recruits as teachers. There is need for more objective studies of the validity and reliability of measures predictive of teaching success in terms of better criteria of teaching efficiency. Measures currently used are disappointing with respect to their validity for selecting the best candidates for teaching. (See TEACHERS, SELECTION OF.)

TEACHER TURNOVER. *Teacher turnover*, in general, refers to the proportion of teachers in a given group at a given time who are new to their respective positions. Investigators vary, however, in their definitions of "new teachers" or "teachers new to their

TEACHER TURNOVER

respective positions." These discrepancies in definition result in sets of figures that rarely agree. For example, one investigator may include in his data only those teachers who have been employed to teach for the first time in a given school or district, but who may either have completed previous teaching elsewhere or never have taught before. Another investigator may include also those teachers who merely changed positions in the same school system. It can readily be seen that the rate of teacher turnover would be greater as reported by the latter investigator.

In the United States during 1930-31, although there were wide variations among states and among districts, in the elementary schools one out of every five teachers was new to his position; in junior high schools, one out of every seven; and in senior high schools, one out of every five. In open country one- and two-teacher schools, two out of every five teachers were new; while in elementary schools in cities of more than 100,000 population, only one out of every twenty teachers was new.

During the depression, the rate of turnover for all types of teachers decreased. While complete data are not available, it appears that the rate of teacher turnover increased slightly during the period of recovery. The mobilization of man power during World War II resulted in a tremendous increase in the rate of teacher turnover.

Vacancies in teaching positions are caused by resignations, dismissals, leaves of absence, or deaths of former teachers; or they may occur from the establishment of new positions.

Among the reasons given by teachers for resignation are (1) acceptance of a teaching position elsewhere; (2) acceptance of a position in another occupational field because of higher salary or because of the interest it holds for the teacher; (3) marriage (in the case of women) and engaging in homemaking; (4) engaging in further study, travel or research; and (5) meeting the demands of personal obligations at home. The reason given most frequently by teachers for resigning from teaching positions is the acceptance of teaching positions elsewhere. Inducements such as higher salaries, better working conditions or working hours, or greater opportunities for professional growth or advancement are responsible for the large

number of teachers who resign to accept other teaching positions. A chance to live with or near friends or relatives is a reason given by a significant number of teachers for changing positions. At times, the teacher may change positions if the new work is more nearly in line with his interests and abilities than is his present position.

Various studies have indicated that teachers are dismissed for insubordination, incompetence or unsatisfactory work, physical or mental disability, immorality, or for political reasons. While turnover is less in states where tenure (*q.v.*) legislation has been enacted to prevent school boards from dismissing teachers for political or other unjustifiable reasons, there is some evidence that certain abuses of tenure legislations may contribute to a higher rate of teacher turnover than is necessary or justifiable. For example, where a probationary period of service is required of teachers before they achieve tenure, some teachers may not be reappointed at the end of the probationary period in order that the number of teachers protected by tenure in a particular school system can be kept as small as possible.

An analysis of the reasons given by teachers for their resignations and of the causes for dismissal of teachers suggests that the rate of teacher turnover may be decreased by (1) paying salaries comparable with the salaries paid for work in other occupations requiring equivalent training and education; (2) protecting teachers through tenure legislation from unjustifiable dismissals; (3) providing more adequate supervision and guidance under creative and sympathetic leadership; (4) creating better working conditions for teachers by having smaller classes and by providing adequate and appropriate educational supplies and equipment; (5) discontinuing the policy of many village and city schools of demanding two years of previous experience as a prerequisite for employment; (6) raising the certification requirements for teachers; and (7) eliminating discrimination against the married woman teacher.

A high rate of teacher turnover leads to school staffs that are composed of teachers who do not remain in the school long enough to become sufficiently aware of the special problems of the school and the community to enable them to achieve the results expected. While it is not known just how long it takes

a teacher to become sufficiently aware of these problems in order to do the task expected of him, no teacher can be expected to make a maximum contribution by being a member of the school or community for a period of only a year or two.

Though it cannot be denied that a high rate of teacher turnover is undesirable since it tends to contribute to instability and inefficiency in education, a negligible rate of teacher turnover may also have undesirable consequences. A school system of any appreciable size that does not continue to employ teachers new to the system is denied the benefits accruing from the influx of new ideas and challenges contributed by new entrants. In one large city in the United States no new teachers have been appointed to the elementary schools and few new teachers have been appointed to the secondary schools for more than ten years because the pupil population is on the decline and the teachers enjoy all the privileges conferred by tenure and a high retirement age. Some critics, impatient with the slowness with which that school system has adopted newer concepts of curriculum and methodology, attribute the resistance to change to the almost complete lack of teacher turnover. (See **TEACHERS' LEGAL STATUS; TEACHERS, SELECTION OF; TEACHERS, STATUS OF.**) W.V.N.

U. S. Office of Education, *National Survey of the Education of Teachers*, Bulletin, 1933, No. 10, Vol. II.

TEACHERS' ABSENCE. Teachers average 6.25 days of absence each year. This average breaks down into 5.28 days for personal illness, .13 days for illness in the home, .21 days for visitations and conferences, .27 days for death in the family, and .36 for other reasons. The absences follow no sequence; for example, there may be no teachers absent today, while twelve may be out tomorrow.¹

Kuhlmann's study showed that 5,260 teachers in 13 cities were absent 5,113 days in the school year for reasons other than their own illness and maladjustments. Illness in the family accounted for 4 per cent; death in the family 10 per cent; visiting and attending educational meetings 15 per cent; miscellaneous reasons 16 per cent. Fifty per cent of the teachers were each absent three days or less, while 29 per cent were not absent at all.²

It is highly essential that absence regulations be flexible, clearly defined, and specifically stated; that they afford protection to the board, teacher, and pupil; that they result in some uniformity with regulations in other systems; that they be simple of administration and of application; and that they imply an adequate system of records.

Types of regulations in use include the Merit Plan—whereby the number of absences allowed is dependent upon each teacher's merit—which is theoretically ideal, but difficult to operate successfully; the plan of deducting the substitute's salary, which does not meet satisfactory criteria for absence regulations; the Group-Insurance and Mutual-Benefit Plans, under which the responsibility for payment to absentee is shifted largely from employers to employees; the Flat-Rate, Fixed Amount Deductible Plan, whereby a number of days are allowed to each teacher for sick leave, but a small amount is deducted from the teacher's salary for each day of absence; the Flat-Rate Plan, which takes care of the great majority of teacher absences by allowing the teacher ten days of sick leave with pay each school year; and the Cumulative Plan, which offers the teacher protection against the expenses of an extended illness. The last-named plan has increased in popularity during recent years, in spite of the fact that it fails to protect the young teacher who has not accumulated many days of sick leave.

A proposed teacher-absence regulation, which combines some of the good qualities found in several of the plans now in use, provides that teachers absent from duty for any reason shall receive their regular salary for the first ten days of absence, one-half their regular salary for absences beginning the eleventh day of absence and continuing through the twentieth day, one-fourth their regular salary for absences beginning with the twenty-first day and continuing through the thirtieth day, and no salary beginning with the thirty-first day of absence. If the

average absence for the teachers in a school or school system has not exceeded an average of ten days of absence during the year for all reasons, the amount deducted from each teacher's salary shall be refunded in full. If the group exceeds an average of ten days, a proportionate reduction in the teacher's salary shall be made for each day of absence.¹

Each of these plans has advantages and disadvantages. The advantage to employers of teachers in selecting only strong and healthy teachers is obvious. (See HEALTH, LEAVE OF ABSENCE, SABBATICAL LEAVE, and SICK LEAVE.) D.H.C. and A.R.A.

TEACHERS' AGENCY—See **TEACHER PLACEMENT**.

TEACHERS' ANNUITIES. An amount of money payable yearly, or at other regular intervals, for a definite or indefinite period is an annuity.

Annuity payments may be considered as added salary allowances to public servants. A small part, usually three to five per cent, of the teachers' salaries is withheld and payment is deferred until after the teacher is retired from active duty. Usually the amount of salary deducted from the teacher's salary is matched by the employing body. This matched amount occasionally is less than the amount deducted from the teacher's salary. The deducted and the matched amounts, taken together, along with the accrued interest thereon, go to make up the teacher's annuity.¹ Both annuity rates and payments are based on mortality tables.² The part of the annuity contributed by the employing board usually is subject to taxation, while the part contributed by the teacher is usually tax exempt. The cost of administration of the annuity fund is usually borne by the state.¹ In case the teacher dies, resigns, or quits the profession, his contributions, with the accumulated interest thereon, are returned to him or his estate.²

In providing funds for teachers' annuities,

state legislatures may appropriate money from the general fund, cause local school districts to make contributions to a state annuity fund, or appropriate funds directly from the state treasury.

Because teachers are considered as employees and not officers of the state, the courts have generally held that a contractual relationship exists between the teacher and the state. Whereas, annuity funds set up for the protection and benefit of municipal and state officers may be eliminated by future legislation, this contractual relationship prevents the state from taking away moneys set aside for teacher's annuities.³ In the absence of statutory authority, it is doubtful whether school districts may deduct portions of teachers' salaries to create an annuity fund.

Teacher annuities work toward raising educational standards, cause seasoned teachers to remain in the service, give dignity to the profession, encourage better qualified persons to enter the field, and provide for retirement and old age. (See **TEACHERS' INSURANCE**, **TEACHERS' RETIREMENTS**, and **TEACHERS' INSURANCE and ANNUITY ASSOCIATION of AMERICA**.) D.H.C. and A.R.A.

TEACHERS, APPOINTMENT OF.

The appointment of a teacher is not complete until he is at work serving his pupils. Assuming that the most approved practice has been followed, the superintendent has recommended the best qualified teacher from the eligibility list. The board has approved the recommendation and authorized the issuance of a contract. The superintendent has sent the signed contract in duplicate to the teacher, who has signed and returned one copy. The contract has been made effective for the opening of school in September, and by its terms the teacher is appointed to serve in the school system and not in a particular building.

When the teacher arrives in the fall, the superintendent, the principal, or their representative helps him to find a location in comfortable living quarters with opportunity

to do scholarly work. He is introduced to a specific assignment of duties and given introductory supervision. Later, his capabilities are analyzed as a basis for more proper placement.

The Committee on Equal Opportunity and the Committee on Tenure of the National Education Association have urged that a uniform contract form be used throughout each state, and that it should state (1) the length of the school term, (2) salary, (3) certificate required, and (4) a date for notification of reelection. These and other provisions for equal protection of the teacher and the board should be stated in legally enforceable language.

Three typical terms of employment which may be provided in the contract are (1) an annual election, (2) a continuing contract, that requires the board to notify the teacher by a specified date if his services will not be required for the following year, and (3) probationary employment. Under the third arrangement, the board may dismiss the teacher at the end of any year during the probationary period without showing cause, but must employ him on permanent tenure (*q.v.*) if it reemploys him at the end of that probationary period. (See **TEACHERS' CONTRACTS; TEACHERS' LEGAL STATUS.**) A.V.O.

TEACHERS' BONUS. For summer-school attendance, travel, outstanding achievement, and similar reasons, payments to teachers, in the form of a bonus, sometimes are made in addition to the contractual salary. Such payment is usually a certain percentage of the annual salary which is uniform throughout a given school system or unit. In order to encourage summer-school study, many boards of education give outright grants, for example a bonus of \$50, usually on the basis of the credit earned. Extension and correspondence work are encouraged in the same way in a few school systems. Such encouragement is provided on the assumption that continued college study leads to increased teaching efficiency. Where this practice is followed, it is important that the teacher's

health be guarded carefully. The bonus plan is used in a few instances to help retain superior teachers over a long period of years.

Approximately 40 per cent of the city school systems encourage summer-school attendance by financing a part of such attendance. In 58 per cent of 605 cities that give direct financial aid for summer-school attendance, teachers are granted a permanent salary increase in addition to the bonus.

Provided teachers attend accredited institutions, school boards and administrative officials, authorities hold, should not specify the particular summer school for the teachers to attend, but the superintendent or principal should feel free to recommend to the teacher certain definite courses which will help meet the teacher's particular needs. The teacher's transcript of summer-school work, it is further held, should be reviewed, and the type of courses taken and the quality of work done should be approved before payment of bonus or of salary increases, or before other recognition is given the work. Many school administrators believe that the advantages claimed for the bonus should be included in the salary schedule instead of using the bonus plan to obtain these results. TEACHERS, CERTIFICATION OF.

In general, teachers are required to have certificates in order to hold positions in the public schools and receive public money in compensation for their services. The most frequently used current basis for certification is the success achieved in appropriate courses, usually of college grade. An older type of certificate generally authorized its holder to teach in any school in the state, and in any department from the kindergarten to the twelfth grade. In contrast, current certificates are more specific authorizations to teach one or more definite subjects or in such departments as kindergarten-primary or senior high school.

Probationary Certificate. A probationary certificate is granted on more limited qualifications as to experience, training, or both, than the highest professional certificate.

of its class. The usual distinction between it and the permanent or unconditional certificate is that the probationary one expires in one, two, or more years, and is renewable for either another specified period or for life, on evidence of professional growth. Frazier reports a marked tendency, in recent revisions of certification requirements, to issue initial certificates to teacher-training graduates on a probationary rather than a permanent basis. The term used here should not be confused with the probationary period of employment of some teachers in city schools.

Life Certificate. As the term implies, a life certificate is ordinarily valid for the teaching life of the holder. However, the implication that the teacher should be able at all times to render efficient service has led to such limitations as a specified age for retirement. Moreover, some regulations provide that after specified periods of disuse of the certificate, the holder must take refresher courses or otherwise show evidence of teaching ability and current professional knowledge and ability, in order to re-enter teaching.

State Certification. State certification exists in the various states, with a few exceptions. In Massachusetts, the town committee keeps full power over certification, although the state issues some certificates to certain groups of teachers and administrators. In California, counties share with the state in making and scoring teacher-examinations, and issue some certificates on the examinations they have administered. Counties may issue certificates, under state control, in Arkansas, Illinois, Mississippi, and Missouri. A few cities located in twelve states, and certain colleges in nine states continue to issue their own certificates.

Reciprocity in Certification. Reciprocity among states in certification of teachers refers to the practice in which a state issues a certificate to an applicant on the basis of an equivalent one which he holds from another state. He may be asked to submit evidence concerning his preparation to help determine whether the two certificates are equivalent. Seemingly because it is regarded as more difficult to determine the equivalence of certificates than it is to evaluate the credits earned in college courses, the latter basis is superseding the former for the issuance of certificates to out-of-town applicants. The number of states that issued cer-

tificates on an exchange basis declined from thirty-eight in 1921 to eight in 1940.

Supervisory Certificate. A recognition of the specialized character of the duties and the training desired of those engaged in supervisory and administrative work has led to the issuance of supervisory certificates. Frazier reports the number of states issuing such certificates as one in 1906 and thirty-one in 1937.

Examination for Certification. In older practice, teachers' certificates were issued to those who were successful in examinations, usually of the essay type. The frequency of this procedure has declined. Frazier reports that only twenty states in 1937 were issuing certificates on examination and only to a small number of persons. However, some large cities, of which New York is an example, use this method of teacher selection. The prerequisite amount of education for admission to teachers' examinations varies from none in a number of states to the possession of a master's degree or its equivalent in other states. (See **TEACHERS' LEGAL STATUS; TEACHERS, APPOINTMENT OF; TEACHERS, SELECTION OF.**) A.V.O.

TEACHERS, COLLEGE—See **COLLEGE FACULTY**.

TEACHERS COLLEGE. An institution for the education of teachers that usually requires high school graduation for admission, offers four years of college grade work, and grants a bachelor's degree at the end of the course. Teachers colleges began to replace the normal schools (*q.v.*) after 1900 and increasingly after 1920. Many new institutions were founded during this time and many normal schools became teachers colleges. The increasing need for more and better prepared teachers after 1900 when the school enrollments of the country expanded rapidly made

necessary the elevation of standards for the teaching profession and resulted in the teachers college movement.

It was clear that prospective teachers needed more than two years of high school before entrance to a professional school, and it was also clear that two years of professional preparation were too little. Students did not have enough time to acquire a good general education in addition to the professional study of education. Therefore, the changes that were involved in the teachers college movement included raising the entrance requirements to four years of high school work, making provisions for the education of secondary school teachers, and lengthening the professional course of study to four years in order to embrace a broad general education as well as mastery of subject matter and an understanding of educational principles and methods. Experimental research and advanced investigation in many areas of teachers college education after 1890 have increasingly built up a resource of organized knowledge and experience that has enhanced the preparation of teachers and made possible the raising of the standards of the profession.

These changes are reflected in the tendency of present-day educators to refer to "teacher education" (*q.v.*) rather than to "teacher training" which connotes a narrow training in skills and pedagogical methods. The trend to teachers colleges is revealed by the fact that in 1920 there were 46 teachers colleges, by 1928 there were 137, and by 1941 there were 185 accredited teachers colleges, most of which were state teachers colleges. Forty-two states have established state teachers colleges; among the most important of the private institutions are Teachers College at Columbia University and George Peabody College for Teachers in Nashville, Tennessee. Many of the teachers colleges, in addition to the bachelor's degree, award the master's degree and a few, the doctor's degree.

The curriculum of the teachers college has expanded to keep pace with and even to lead the expansion of educational services in the schools of the country. The curriculum of a large teachers college includes a wide range of courses to meet the needs of regular teachers in all areas of the elementary schools and secondary schools, of administrative officers

on all levels, and of special functions of many kinds. In addition to the subject matter fields a teachers college offers work in the foundations of education common to all educational workers (philosophy, history, psychology, and sociology of education); work in special branches of curriculum, administration and guidance in different types of schools and institutions; and opportunity for observation, participation, and practice in actual teaching situations. TEACHERS' CONTRACTS. The teacher's contract creates and conditions the teacher's status, and justifies her power to act *in loco parentis* (*q.v.*). The legal status varies from state to state, and within a state among different types of districts. Some states have standardized contract forms for local school boards, and others have no contract forms at all. Some contracts are short simple documents, while others enumerate scores of duties imposed upon the teacher. In some states there is no control over the power of the local school board to contract with teachers; other states control the power of appointment and dismissal, and stipulate specific items to be included in the teacher's contract. Universally, some type of certificate is required of a teacher (See **TEACHER'S LEGAL STATUS**). Whether the certificate must be available at the time of entering the contract or merely prior to starting teaching is frequently a matter of statutory language.

While there are some special aspects about teacher's contracts, the general law of contracts applies to them. As in all cases, the contract must comply with any specific statutory terms, as to form, debt limitations, and the like. While most statutes require that the teacher's contract be in writing, apart from statute an oral contract is generally valid. Other normal contract law rules also apply. It must be definite; if the salary is left to

future agreement, it is too indefinite. The parties must be competent to contract. This means that the contract must be approved by the school board, *as a board*, and not merely by its members individually. Nor can approval of the contract be delegated to the superintendent. There must be adequate consideration, as well as an offer of employment and its acceptance. Also, and of great importance, are the "silent terms" of the contract, the statutory provisions and the board's rules and regulations, which are parts of the contract even although not specifically mentioned.

Types of Contract—Tenure. In general there are two types of teacher's contract laws, one of statewide application, the other of local application. Among the *state-wide and uniform laws*, there are few characteristic types: (a) annual elections of teacher, or a complete absence of all legislation, in which event the annual election procedure is generally followed; this exists in eleven states; (b) long-term contracts, which may be awarded for periods of more than one year, exist in two states; (c) the continuing contract, whereby a teacher continues for the next year if she has not received notice of termination by a given date. This type of statute, which exists in some ten states, carries no assurance of security because it does not forbid dismissals without cause or for arbitrary reasons, but merely makes the school board act within a specified time. Some of the more recent continuing contract laws really are permanent tenure laws in effect; (d) permanent tenure after a probationary period of from one to five, but generally, three years with dismissal only after notice of cause, and generally on hearing and trial. This type of law exists in seven states. *Non-uniformity applicable* provisions in eighteen states carry different combinations of tenure in some regions of the state, optional tenure in others, mixed with continuing contract and annual election programs in still other parts of the state.

In addition to state systems, there are two types of local tenure plans. In ten states, there are state statutes creating local tenure plans applicable to particular localities only, and in at least nineteen cities local tenure has been created by local action.

According to a June 1942 study of the Na-

tional Education Association, city teachers, generally speaking, have some form of tenure protection in thirty-seven states, and rural teachers, in twenty-four states.

Permanent tenure legislation is of recent development and is intended to free teachers from political, personal, or commercial domination, to protect them against unjust and arbitrary dismissal, to provide some reasonable personal and academic freedom, and to encourage experienced teachers to remain in their profession rather than seek other and more remunerative employment. It has been universally upheld as constitutional. In some places, it has been unpopular with school boards who have sought to circumvent its effect by requiring signed but undated resignations, or have dismissed teachers before the completion of probationary terms so as to prevent the vesting of tenure. Such practices have been declared improper in at least two states: *Hosford v. Board of Education of Minneapolis*, 201 Minn. 1, 275 N.W. 81 (1937); *Briney v. Santa Ana H. S. Dist.*, 131 Cal. App. 357, 21 Pac. (2) 610 (1933).

Where tenure laws are set up in terms of contracts, they partake of the protection of the contract clause of the federal constitution (See EDUCATIONAL LAW AND LEGISLATION; DARTMOUTH CASE; TENURE) and are thus immune from subsequent legislation. *State ex rel Anderson v. Brand*, 303 U.S. 95 (1938).

The latest available figures, prepared by the National Education Association as of May 1, 1942, show that 44.6 per cent of the teachers in the country have tenure protection; 20.9 per cent are under continuing contract plans; 7.1 per cent under long-term contract arrangements; 6.6 per cent are subject to annual election; and 20.8 per cent are at the mercy of boards subject to no legislative restrictions.

Dismissals. Apart from statutory restrictions, boards generally have the power to dismiss teachers. But even in the absence of statutory protection, it is widely held that such dismissals before the end of the contract term must be for cause and cannot be arbitrary. Tenure statutes place controls upon the school board's untrammelled right of dismissal, generally restricting dismissals to those cases involving causes which are enumerated in the statute. Commonly specified causes for removal include: disobedience of board rules,

if the rules are reasonable and within the board's authority to adopt; incompetence, in which case the burden of proof is upon the school board; neglect of duty; misconduct; and immorality (in some cases it has been held that a mere charge of immorality is sufficient cause). The states are in conflict as to whether, apart from statute, marriage is cause for dismissal; in tenure cases the majority view seems to hold that it is not.

Courts have had occasion to review dismissals of teachers for political activity. Merely by becoming a teacher, one does not lose his rights of citizenship or of the free expression of his religious, social, political, or other convictions. Apart from the restrictions laid down in such legislation as the Hatch act (*q.v.*), teachers may engage in political activities outside of the classroom. The troublesome issue arises when the dismissals are attributable to membership in political or other groups espousing nationally or locally unpopular views, e.g., communism, socialism, pacifism, evolutionism, or equality of races. Normally, such teachers are dismissed on fictitious charges of incompetence, disobedience, or some other alleged statutory ground for dismissal. Judicial affirmation of such dismissals—whether for the truthful or the fictitious reason, or for indefinite causes admittedly unrelated to classroom efficiency—is destructive of that security and independence so essential to the full performance of a teacher's function in a democracy. (See ACADEMIC FREEDOM.)

Generally, tenure statutes assure teachers of the right to a notice of the charges and the opportunity for a hearing before dismissal; where such rights are allowed, no dismissal can be made legally without following the statutory procedure. Where the statute gives no right to a hearing but specifies causes for removal, it has been held frequently that a hearing is still necessary. The procedure in such hearings is informal and unfettered by technical rules of evidence.

Damages. An improperly dismissed teacher may recover damages sustained thereby, which under normal circumstances could be the contract salary. However, a dismissed teacher is under a duty to mitigate these damages to the best of her ability by making reasonable efforts to obtain work of the same general character if not too remotely situated

from home. A dismissed teacher cannot refuse to take other similar employment and expect to recover the whole amount of her contract salary. Any such other earnings during the original period of the contract must be deducted from the contract salary to reach the amount of allowable damages.

Where a teacher who has earned tenure has been dismissed improperly she is entitled not only to damages, but also to reinstatement to her former position. Tenure is not only a guaranty against arbitrary dismissal, but is also a protection against arbitrary or unreasonable demotions, although tenure does not freeze teachers into specific jobs or assignments.

Abolition. If a contract is for a definite term, it is generally held that the position legally cannot be abolished prior to the termination of that term. However, tenure rights do not bar abolition of a position, if done in good faith. In some laws, priority of re-employment is guaranteed to teachers with tenure whose positions have been abolished. TEACHERS CREDIT UNION — See LOAN FUNDS.

TEACHERS' HANDBOOK. So that teachers may constantly evaluate their professional knowledge and have a book for quick reference to information needed in the teacher's daily tasks, there is a real need for a compact compilation of important facts, principles, theories, and data in each of the various phases of education. It is usually the purpose of a teachers' handbook to meet these needs. A good example of such a handbook is the one written by Elsbree, Halsey, and Elsbree.²

Another purpose of the teachers' handbook

is that of stimulating teachers and others interested in the profession to further study in the field of education. Such purposes as providing a means for self improvement among teachers, stimulating parent-teacher association programs, and serving as a ready reference for students in education are proposed for such books. The usual contents of these handbooks are in the form of brief statements which frequently consist of questions and answers. Those handbooks which are written by boards of education, superintendents, and teacher committees generally consist of a list of directions, suggestions, statements of policy, and rules of the school system.¹

TEACHERS' HEALTH. A survey of the studies of the health of teachers shows that men are absent less frequently and for shorter periods than women. Ailments peculiar to women have little bearing on teacher absence.

Great inconsistency is shown in the relation of sickness rate to age. In some cities the rate increases steadily with age; in others there is no correlation between age and illness; and in still others the rate declines with increase in age. On the whole, however, the weight of evidence seems to indicate that the sickness rate of school teachers increases slightly with age.

So far as the death rate is indicative of the level of health, teachers, as a class, are remarkably healthy. When the number who are sick and the length of absences are compared with similar records of industrial workers and clerical groups, the health record of the teacher remains superior. The most frequent causes of teachers' illness are diseases of the respiratory system, such as colds and influenza, although teachers are not more subject to these diseases than are other indoor workers. The opportunity for contagion in the classroom makes the incidence of colds more serious among teachers than among workers in shops and offices. Illness caused by digestive disorders is less common among teachers than among workers in other fields. Tuberculosis

does not appear to be significant among teachers, but laryngitis is considered by some health specialists as a true occupational disease of teachers. Tonsillitis is also a common cause of absence.

Long expensive illnesses are relatively infrequent among teachers. Nervous disorders are more common among women than among men. Absences due to nervous disorders increase with advancing age.

On the whole, the teacher has a relatively good chance for a long life and a comparatively low sickness rate in comparison with workers in other fields. The "average teacher" will have a succession of minor ailments in a life comparatively free from serious risks.¹

A recent report indicates that 23 per cent of classroom teachers are in excellent health, 46.5 per cent are in good health, 10 per cent are in fair health, 5 per cent are low in vitality, while 2.5 per cent are in chronic ill health.² (See **TEACHERS' ABSENCE**.)

TEACHERS' INSTITUTE—See **TEACHERS' MEETING**.

TEACHERS' INSURANCE. A plan whereby teachers are guaranteed a financial payment or indemnity for chance occurrences such as loss of job, loss of health, or injury; and the payment of a stipulated sum to a specified beneficiary in the event of death may be called *teachers' insurance*.

Under the group plan, teachers are insured as a group rather than individually; the rates are lower, and the protection is less satisfactory. Many teachers have found the group-insurance plan less satisfactory than a good state retirement system.²

Whereas industrial employers may require all their employees to enroll for group insurance, such compulsion is impractical for teachers. Teachers' membership in group insurance plans has always been voluntary despite the resultant difficulty of maintaining a sufficiently large group. In industry the employer usually contributes to the payment of the group-insurance premium, but teachers

usually pay the total cost of their own group insurance.³

Some of the advantages of group insurance are (a) all members of the teaching group are usually eligible without a medical examination, (b) teachers are usually permitted to convert their policies to ordinary insurance upon withdrawal from the staff or, in some cases, from the profession, (c) in most systems new members may enter at any time, (d) the typical group health-and-accident insurance policy covers every disability of the entire teaching personnel.³

Some of the disadvantages are (a) the insurance company usually reserves the right to cancel the master policy; (b) younger teachers are seldom interested in group insurance, and may be able to buy individual insurance at a cheaper rate; (c) in many instances, teachers must give up their group insurance upon retiring from active teaching.

As for individual insurance, the commercial companies naturally try to sell the type of insurance that is most profitable. Teachers should realize this fact and ask themselves certain questions such as the following before purchasing insurance: What are my insurance needs? Which is more economical, the stock or mutual type of insurance? If I cannot purchase all the insurance which I need, which type should I purchase first?

One of the worst threats to economic security is permanent disability. Commercial companies offer so many types of coverage against loss of income from disability, both temporary and permanent, that it is difficult for the teacher to know when he is getting adequate protection. Most of the policies for accidents are not only written for a limited period of time, but may be cancelled at the option of the company. Cancellation of insurance against disability should not be allowed; income should be guaranteed for life; premium payments should be waived during disability; waiting periods after disability should be short; and agreement as to what constitutes disability should be clear.¹ (See **TEACHERS' ANNUITIES, TEACHERS' RETIREMENT, and TEACHERS' INSURANCE and ANNUITY ASSOCIATION OF AMERICA.**) D.H.C. and A.R.A.

TEACHER'S LEGAL STATUS. The teacher is surrounded by all sorts of statutory, administrative, and customary provisions which condition the performance of duty.

Certification. All states now require teachers to possess certificates or licenses issued by appropriate authorities, generally the State Board of Education or State Superintendent, before they may be permitted to teach. Recent years have witnessed a tendency toward centralization of the certification functions; in 1893, teaching certificates were issued by state-wide agencies in only 3 states, but by 1933, 39 states operated on a centralized basis. With this movement has grown another for the raising of requirements for licensing and for differentiation of certification requirements. While local communities may establish additional qualifications, normally the state requirements are determinative. Among the general requirements, over one-third of the states prescribe citizenship, and over one-half a certificate of good health; generally, a high school education, and an age of 18 years is necessary, although frequently college education is now required. Professional requirements are of varied sorts; courses in school law and in state or federal constitutions and history typify one form of course content, while subject matter and methodology courses typify another. Occasionally, examinations are given to test professional competence, but

TEACHER'S LEGAL STATUS

by and large certification is based on credentials; reciprocity of certification among states is not as common as it might be. Renewals of certificates are frequently based on continued in-service education. The power of revocation of certificates generally exists in state authorities, and in about one-quarter of the states in local authorities. (See **TEACHERS, CERTIFICATION OF.**)

Salaries. About 24 states have some type of mandatory minimum-wage salary laws for teachers, slightly over half of which are of state-wide application. Most of these laws were enacted during and following the First World War, when a serious emergency was caused by teacher scarcity. There is a widespread practice of establishing salary differentials based on sex. Although as early as 1914, the National Education Association went on record as being opposed to such differentials, only ten states have adopted laws forbidding such discrimination against female teachers. Provisions common in some states setting up different salary schedules for white and colored teachers have been declared unconstitutional [*Alston v. School Board of City of Norfolk*, 112 Fed. (2) 992 (1940), *cert. den.* 311 U. S. 693 (1940)]. And while there has been an increase in salary levels from an estimated average annual earning of \$256 in 1890 to an estimated average annual salary of \$1,360 in 1940, the increase does not compare favorably with the general increase in wages except in the last decade. The general low level of teachers' salaries, particularly in rural areas, is one of the reasons usually given for the large turnover of teachers. (See **TEACHERS' SALARIES.**)

Pensions and Retirement. Retirement laws differ among states; but in general actuarially sound systems provide for mutual contributions to the fund by the teacher (almost universally in terms of a given percentage of salary) and by the state (in equal amount).

The constitutionality of teachers' pension systems has been upheld as a means of obtaining a better type of personnel through assuring the teacher and his dependents some degree of security on superannuation or disability. By 1940 there were 33 state-wide pension or retirement systems, and at least 65 local ones in 26 states, 9 of which have

no state-wide system, all together covering some 65% of the teachers of the country. In many of these, the retirement benefits are very inadequate. There is no general uniformity among these various systems, some of which are not even on a contributory basis and many of which leave much to be desired in soundness; only eleven have a compulsory retirement age. Few systems include non-certificated school employees or the professional staffs of state universities or teachers colleges. (See **TEACHERS' RETIREMENT.**)

Working Conditions. The teacher operates in terms of not only her contract, but also the school code and the school board bylaws and regulations, although she may never have seen either of them. This means that her contract has read into it all the requirements of the statutes and state board regulations, and all the restrictions of the local board's rules. Some of these rules impinge very heavily upon the personal and private life of the teacher. Among administrative "blue-laws" are local contract provisions forbidding teachers to keep company with "sorry young men," provisions whereby the teacher agrees not to attend dances, and not to marry; other contracts require the teacher to spend week-ends in town "except at such intervals as the superintendent may designate." Other contracts regulate the length of skirts and the amount of rouge and lipstick. Perhaps the prize one requires a teacher to sign a statement: "I promise not to fall in love." Owing to the insecurity of so many American teachers, teachers are helpless against school boards which regard appointments as favors. No warrant exists in law for it, but it is well-known that appointments frequently are dictated by such personal considerations as religious beliefs, nationality, kinship to influential board members, and marital status, rather than by professional consideration. For many teachers there is no such thing as privacy or the development of an individual personality; the teachers' social and intellectual activities are closely restricted. However in school systems where appointment is on the basis of examinations similar to those in the civil service there is less danger of these conditions existing.

Some school boards insist upon what is

known in labor circles as a "yellow-dog" contract. These agreements not to join a labor union have been upheld [*Seattle H. S. Chapter of American Federation of Teachers v. Sharples*, 159 Wash. 524, 293 Pac. 994 (1930)].

Some communities have been sustained in their refusal to employ married women as teachers and in the dismissal of female teachers who married after they were employed. Such policies have found widespread condemnation, and seem to be likely to diminish at least during periods of shortages of teachers. (See also HATCH ACT; IN LOCO PARENTIS; LIABILITY; LOYALTY OATHS; TEACHERS' CONTRACTS; TEACHERS' STATUS.)

TEACHERS' MEETINGS. To facilitate the general administration of the school and to improve the teachers in service constitute the twofold function of a typical teachers' meeting. General professional meetings, grade meetings, professional-study meetings, and departmental or subject-matter meetings are, in general, the most frequently held types of teachers' meetings. The first type (professional meeting) is in some places called the *teachers' institute*. This is the name given to the type of meeting in which the teachers report for duty one or more days before school opens for the purposes of orientation, formulation of aims and objectives, and outlining methods of procedure. In some schools, meetings of this sort are held periodically throughout the session, while in others they are held only at the beginning of each session of school. All teachers in the school are expected to attend these meetings. A part

of the time is generally used for becoming better acquainted.¹

When problems arise which are peculiar to the teachers of a particular grade (fourth-grade teachers, for example) the supervisory officials may call what is termed a *grade meeting*. Such meetings obviously are practical only when there are at least 8 or 10 teachers in a given grade. The type of meeting in high school which corresponds with the grade meeting in the elementary school is known as the *departmental meeting* or *subject-matter meeting*. Where there is departmentalized teaching in the elementary school there is occasion for the subject-matter type of meeting.

The professional-study meeting usually centers about some problem which should be approached from the point of view of both theory and practice. The teaching of reading, for example, can be studied intensively at a given number of meetings. The best prepared teacher in the field may conduct the program of the meeting. This instructor may ask the other teachers questions, give them assignments, and call upon them for reports. The problem is usually selected by the common consent of all concerned.

Of the many methods used in conducting teachers' meetings, some are more effective than others. The following methods were reported in the *National Survey of the Education of Teachers*: 1. scheduled addresses by local staff members; 2. scheduled addresses by "outside" speakers; 3. group discussion led by local staff members; 4. group discussion led by an "outsider"; 5. scheduled addresses and group discussion by local staff members; 6. scheduled addresses by "outside" speakers, followed by group discussion; 7. demonstration teaching with a group of children by local staff members, followed by discussion; 8. demonstration teaching with a group of children by an "outsider", followed by discussion; 9. "clinical" demonstration by local staff members of a process or an activity not involving teaching problems; for example, keeping attendance records, explaining technicalities of radio transmission and reception, constructing a bulletin board; 10. "clinical" demonstration by an "outsider" of a process or activity not involving a teaching problem; for example, the preparation of a case study of a pupil referred to a child guidance clinic; 11. exhibits of books, equipment, special materials of instruction or

pupils' work, conducted by local staff members; and 12. exhibits of books, equipment, special materials of instruction or pupils' work, conducted by "outside" agencies.

TEACHERS' PENSIONS — See TEACHERS' RETIREMENT.

TEACHERS, RATING OF. In order to promote teaching efficiency, to improve teachers in service, to help determine teacher promotion and dismissal, to aid in supervision, and for other reasons, many superintendents feel that it is desirable to rate teachers. To promote teaching efficiency is usually considered the most important of these purposes for rating.

It is the duty of the superintendent to rate the teachers, since their selection is his responsibility. In actual practice, however, superintendents select the majority of teachers, but the principals and supervisors usually rate them. Teachers are also rated by their pupils, teaching colleagues, school patrons, the public in general and boards of education. Frequently teachers rate themselves.³

Teacher rating, in spite of the difficulty involved, is still a useful tool in the hands of a skilled rating official who can use it wisely. Many school officials are recognizing the fact that teachers can profitably be encouraged to rate themselves. It is significant that there is a low correlation between teachers' self-evaluation and principals' evaluation of the same teachers.²

A *score card* is a type of rating device whereon definite numerical values are assigned to each factor, and the rater checks the number which best expresses his opinion of the teacher as regards the factor. *The Carrigan Score Card for Rating Teaching and the Teacher*, prepared by Rose A. Carrigan and published by World Book Company, 1930, is a good illustration of score cards by which teachers are rated. (Items below quoted by permission of the publisher). It represents one form of the impression method.

The Carrigan Score Card presents a series of questions on the teacher's traits and procedures to be answered by the supervisor. The score card is divided into two parts: *Part I, Teaching*, and *Part II, The Teacher*. Part I is further subdivided into three major factors: *A. The Background or Workshop*; *B. The Work*; *C. The Child*. For each factor there are a number of specific questions to be answered. Thus, *The Work*, for example, is evaluated in terms of eight separate questions: *I. Was the subject matter, so far as it was under the control of the teacher, worthwhile?* *II. Was the specific aim apparent, definite, and of sufficient worth?* *III. Was the organization good?* *IV. Was all the time profitably employed, thus indicating that the teacher had a proper sense of values?* *V. Did the proportion of individual response in the class prove the teaching successful?* *VI. Was the work wholly cooperative, or merely a guessing game in which the children tried to find out what answers the teacher wanted?* *VII. Was there a checking of results?* *VIII. Was there suggested any vital connection with a future activity?* Though the items to be rated appear as questions, the responses are to be expressed in numerical terms. In answer to the question, "*Was there a checking of results?*" the supervisor is expected to give the teacher a score ranging from zero up to a maximum of forty. Not all questions are equally important in determining the final rating. The question "*Were there attempts to beautify it (the room) in any simple, inexpensive way?*" has a maximum score of 15 while the question, "*Was there a satisfactory proportion of individual children who, throughout the entire period, were absorbingly interested in the work and were putting forth effort?*" has a maximum score of 100. These maximum scores represent the value which the author of the score card attaches to the influence which the rating on that question should have in determining the total score.

The tendency, however, is towards the use of rating scales and away from the score card. A *rating scale* is a device for comparing the efficiency of the teacher in a school system with the other teachers or with an accepted standard. The Tuscaloosa County (Alabama) Teachers Association, for example, has prepared a *Teacher Rating Scale* to be used in the Tuscaloosa County Schools.

This scale is planned in terms of eight major categories; namely, *I. Personal Characteristics; II. Ability to Plan and Teach; III. Classroom Management; IV. Professional Status; V. Extra-Curricular; VI. Promptness; VII. Professional Memberships.* Each of these aspects of the teacher's ability is evaluated in terms of a number of more specific items, each of which is rated on a five-point scale ranging from *superior to good to average to fair, to poor.* Thus, *Personal Characteristics* has twelve items as follows: 1. *Personal appearance; 2. Voice and speech; 3. Emotional stability; 4. Initiative and originality; 5. Ability to plan and execute; 6. Willingness to work and accept responsibility; 7. Loyalty and co-operation; 8. Attitude toward supervision; 9. Enthusiasm; 10. Consideration for pupils; 11. Health; 12. Tact.*

Rating Scales have also been prepared for administrators and supervisors.¹ On the rating scale which San Francisco (California) uses for measuring the efficiency of administrators there are six major categories: *I. Personal Characteristics; II. Leadership; III. Professional Qualifications; IV. Clerical Work; V. Administration; VI. Supervision.* The administrator is rated with respect to each of these six categories by means of a five-point scale; namely, 1. *Outstanding; 2. Very Good; 3. Satisfactory; 4. Unsatisfactory; and 5. Failing.* To assist the person who is to rate the administrator, there are listed a number of specific factors which should be considered; provision is made for including other factors, too, in the rating. For example, under *V. Administration*, the following factors are indicated: 1. *Ability to understand problems and to make prompt decisions; 2. Check on attendance and tardiness; 3. Classification of pupils and assignment of teachers; 4. Control of pupils (order and discipline); 5. Curriculum adjustment; 6. Distribution of books and supplies; 7. Effective use of building (rooms, library, auditorium); 8. Guidance of extra-curricular activities; 9. Health program; 10. Plan for janitorial service; 11. Program making; 12. Safety program; 13. Sense of order and system; 14. Traffic control (in building or out of building); 15. Understanding of relative values; 16. Upkeep and appearance of building; 17. Use of yard and play facilities.*

The preparation of score cards and rating

scales for rating teachers and administrators stems from the widespread dissatisfaction with traditional methods of rating which rested so largely on the superior officer's vague likes and dislikes, sometimes with respect to traits which are unimportant or even irrelevant. At the very least, these scales improve ratings by indicating the factors which should be considered when teachers and administrators are evaluated. The specificity of the items and the ratings reduce, to some extent, the complete subjectivity of the ratings, even though they do not necessarily lead to absolutely objective ratings. That the total score can usually be analyzed in terms of ratings on specific items facilitates diagnosis of failure and also the planning of a corrective program.

It is generally agreed by those who have used rating scales and score cards for teachers and administrators that these measuring instruments have improved the rating process but that there is room for even further improvement. Unless criteria are suggested as the basis for judgment, the ratings continue to represent the judge's personal opinion. Thus, what one judge considers superior initiative and originality may be considered by another to be only average. Some critics have protested that these scales are inadequate, for they include only these traits that are readily rated in numerical terms. They point, for example, to the fact that some rating scales overlook such significant and intangible traits as the teacher's ability to inspire genuine and persisting interests in significant problems, and his influence on the development of other eminently desirable traits in his students. There is always danger that the use of a rating scale may keep the superior teacher from going beyond the current conception of what a good teacher is. On the whole, any system of teacher ratings is more effective when it is used as part of a larger program for teacher improvement than when it is used solely as a basis for classifying or grading teachers with respect to their ability. TEACHERS' RETIREMENT. In order to protect pupils by removing inefficient, disabled, and senile teachers, to give teachers a sense of economic and social security, and to attract exceptional students to teaching, more than fifty per cent of the states, and Hawaii, have set up well-organized systems of teacher retirement. Although the majority of the teachers in the United States are protected by some type of retirement system, a large number of teachers still have no such protection.

Colleges and universities, too, have their retirement plans. Beginning with Colorado colleges in 1890, the movement spread until by 1934, 23 per cent of all such institutions in the United States and Canada, employing 47 per cent of the college teachers in these two countries, were making some provision for teachers' retirement. The following plans are in operation among colleges: (1) group contracts with commercial insurance companies; (2) the Carnegie free pension plan set up in 1905, which is now limited in its application; (3) the Teachers Insurance and Annuity Association (*q.v.*) incorporated in 1918, which is a cooperative plan of deferred annuity payments; (4) state teacher retirement systems which include the higher educational institutions under state control; (5) church pension and retirement plans which are open to ordained ministers who serve on the faculties of the colleges affiliated with such churches; (6) plans organized and administered by and within individual institutions. Frequently the benefits of college pension and retirement plans are open to other than faculty members.

Teachers' retirement plans can be divided into three major groups: the free plan, or pension, wherein all payments to teachers are made from the general fund; the contributory, or mutual-benefit plan, in which the retirement fund consists of the accumulated teacher contributions; and the joint-contributory plan, which consists of contributions from both the teacher and the employing body.

The word *pension* is properly used to refer to the financial reward given to individuals who retire from the school system or from the profession. The teacher makes no contribution to the pension fund out of his salary. A teachers' annuity fund or a teachers' retirement fund, to which the teachers contri-

bute out of their salary, is sometimes referred to erroneously as teachers' pension.

The courts have held that teacher-pension legislation does not violate the Fourteenth Amendment; that it does not constitute class legislation, because teachers are a class set apart by their vocation; and that pensions do not constitute the expenditure of public funds for private purposes, because education is a public purpose.

The current drift is away from the pension or outright grant and toward contributory plans wherein the teacher shares the cost, for this has proven more satisfactory and financially more successful.

The present tendency is to set arbitrary age limits for optional retirement, usually 60 years after approximately twenty-five years of service. The age for compulsory retirement is 65 or 70. The practice of requiring those who teach beyond the optional age limit to pass a medical examination is increasing.

Two of the chief weaknesses of the state teacher-retirement systems are the unsound reserve basis of many of the systems and the failure to provide for periodic actuarial check-up. Thus, one state system has all its reserve funds invested in the securities of the state. (See **TEACHERS' ANNUITIES; TEACHERS' INSURANCE; TEACHERS INSURANCE AND ANNUITY ASSOCIATION OF AMERICA.**)

TEACHERS' SALARIES. The average salary of teachers in the United States in 1913 was \$512, which was 60 per cent less than the average income per person gainfully employed. Teachers' salaries, along with those of other public employees, increased steadily during the middle 1920's but remained from 20 to 25 per cent below the national average income per person gainfully occupied. The low point for gainfully employed workers came in 1933; for teachers, in 1934.¹

TEACHERS' SALARIES

As compared with the earnings of salaried and wage-earning persons, the earnings of teachers are definitely below those of salaried workers and slightly above wage earners. For all city teachers the average salary in 1940 was 7 per cent higher than in 1929. For rural teachers the average salary in 1940 was still 7 per cent lower than in 1929. Throughout the entire depression period, the average salary for teachers was lower than the average salary of all federal, state, or city government employees.

During the period 1935 to 1940, price levels were more or less stable, but beginning in 1941 prices began to soar rapidly. Teachers, whose average salary has risen more slowly than the cost of living, have been and still are suffering an increasing loss in purchasing power. The salary that was worth \$1,000 before October 15, 1941, was worth only \$914 on November 29, 1941. This decrease in purchasing power is increasing at an accelerated rate so that before the end of 1942, unless teacher pay is substantially increased, there will be further significant shrinkages in the purchasing value of teachers' salaries.¹

Notwithstanding the increasing use of single-salary schedules, secondary school teachers continue, on the average, to receive higher salaries than do elementary school teachers. The average salary of elementary school teachers in cities is 13 per cent less than the average for junior high school teachers, while senior high school teachers average 22 per cent more than teachers in the elementary schools. In rural areas the single woman teacher who is rooming and boarding has an average total income of \$830; the married man teacher who rents a home has an average total income of \$1,400. On the average, urban teachers receive \$1,900 annually, rural teachers \$830. In

accordance with estimated average earnings during a working lifetime, public school teaching has been ranked 11th among a group of 16 occupations.²

Occupations ranked above public school teaching are medicine, law, dentistry, engineering, architecture, college teaching, social work, journalism, ministry, and library work. On the same basis, occupations falling below public school teaching are the skilled trades, nursing, unskilled labor, farming, and farm labor.

Single Salary Plan. There are, in the main, two distinct types of salary schedules for teachers. In the position-automatic type of schedule, the teaching position in a school system, rather than experience and preparation, determines salary, while in the single-salary plan the same salary is paid to all teachers who render approximately equal service and have approximately equal professional qualifications, experience, and preparation, irrespective of their teaching positions. Thus, elementary school teachers are paid as much as are equally qualified secondary school teachers. Under the single-salary schedule, no differential in pay is made between men and women teachers who have about the same preparation and experience. Except in very large schools, the salary schedule is not applied to special employees, principals, and superintendents.

The manner in which these two types of schedules operate is seen from an examination of the following table: In Washington, D. C., an elementary school teacher who is receiving the maximum salary for that position may get a higher salary by being transferred to the high school. In Miami, Florida, however, an elementary school teacher does not receive any more money by being transferred to a high school.

Position-Automatic and Single-Salary Types of Salary Schedules
1941-42

Type of Schedule	City	Training	Elementary School Teachers		Senior High School Teachers	
			Minimum Salary	Maximum Salary	Minimum Salary	Maximum Salary
Position-Automatic	Washington, D. C.	Bachelor's Degree	\$1,400	\$2,200	\$1,800	\$2,800
Single-Salary	Miami, Fla.	Bachelor's Degree	1,020	1,800	1,020	1,800
		Master's Degree	1,120	1,900	1,120	1,900

TEACHERS, SELECTION OF

During recent years there has been a widespread movement on the part of boards of education to adopt a single-salary plan. Of 150 salary schedules adopted recently, 59 have a single-salary plan which makes no distinction between the salary paid to elementary school teachers and that paid to secondary school teachers. According to these schedules men teachers and women teachers of equal training receive equal salaries. In 54 school systems, secondary school teachers are better paid than elementary school teachers, but there is no differential between men's and women's salaries. In the remaining 37 school systems, secondary school teachers are better paid than elementary teachers, and men teachers are paid better than are women teachers who hold similar positions.

Under the single-salary plan, it is difficult to compensate for special merit. The practical impossibility of measuring merit objectively and the difficulty of recognizing superior merit in teachers render the application of the merit principle difficult on the basis of a single-salary schedule.

The single-salary plan has the advantage of making it possible to secure a better teacher for the elementary schools, since under its provisions of equal pay for equal service and equal qualifications, elementary school teachers are paid the same salary as are high school teachers. This schedule also enables the superintendent to reassign his teachers to positions where they will give the best service without jeopardizing their incomes. The single-salary schedule tends to eliminate cliques and helps promote staff unity.

Because it is simple to operate and offers no opportunity for favoritism, unless the merit principle operates in its administration, the automatic type, single-salary, schedule is often favored over the position-automatic type. If the pay is based on position regardless of preparation, however, those who are desirous of promotion will tend to look toward the administrative positions which offer better pay. Where increments are based partly on preparation and experience, it is much easier to retain superior personnel in the departments where they may render the best service.⁴

TEACHERS, SELECTION OF. Procedures have been developed in large cities which help discover well-qualified teachers and induce them to remain in the teaching profession. Some of these procedures should have a wider use, and newer ones of promise should be developed. The Research Bulletin of the N. E. A. for March, 1942, suggests six steps for the selection and appointment of teachers (1) stating the qualifications and disqualifications that govern eligibility; (2) forecasting the probable needs for new personnel in the near future; (3) assembling applications, both voluntary ones and those secured by recruiting; (4) assembling the written and personal data concerning the candidates; (5) selecting the individuals to be nominated to the board; and (6) appointing of the candidates by the school board.

The school board should state the qualifications desired for various positions. The superintendent should forecast the needs, assemble the applications and data, and select the individuals to be nominated to the board. Appointments should be made by the board only on his nomination. That is done currently in approximately eighty-three per cent of the city school systems in the United States.

In professional practice, the school board states the standard qualifications that are to govern the eligibility of teachers for each type of position and the accepted policies for selecting the personnel. Only qualifications as defined in these standards should be considered in selecting candidates. Local boards must set their standards of eligibility for teachers at least as high as the legal requirements, but may set them higher. However, it is not considered good policy for them to discriminate against non-local residents, older persons, married women, or members of certain races, faiths, or parties.

Standards of preparation for admission to teaching positions are generally higher in larger cities than in smaller places. New elementary school teachers are seldom required to have less than two years of college preparation. Fifty-eight per cent of the cities from 2,500 to 5,000 population require four years of preparation for teaching in elementary schools, and 88 per cent of them require the same amount of preparation for junior high school teachers. Five years of preparation for senior high school teaching is the standard in 28 per cent of the cities over 100,000 in population, but in only 7 per cent of the cities from 2,500 to 5,000 population. A greater number of large cities than smaller ones have maximum age limits for entering the teaching profession. The median limit is close to 40 years for both elementary and high schools. Married women teachers are employed currently in about 40 per cent of the cities. Fifty-one per cent give preference to local residents; this is done to a greater extent in large communities than in smaller ones.

Data collected for 1931 and 1941 suggest a qualitative improvement in the preparation of teachers coincidental with the greater length of time spent in preparation. Standards for certification have been increased by state agencies, by regional accrediting associations, by the selective admission of candidates to teachers' colleges, and by the improved training offered there. Longer professional training is replacing the former emphasis upon previous teaching experience.

The salary committee of the N. E. A. in 1923 opposed the requirement of previous teaching experience for candidates for new teaching positions. It seems inconsistent with the best educational theory to require teachers to receive their initial experience in schools with meager facilities and no supervision, in order to qualify them to teach in larger schools where supervision is well defined. Seventy-one per cent of the cities of more than 100,000 population require no previous teaching experience of candidates for elementary school positions. In senior high schools, 51 per cent of the same cities require no previous experience. A smaller proportion now of the larger cities than of the smaller ones demand previous experience of candidates for teaching positions.

Internships (See INTERNSHIP PLAN OF TEACHER EDUCATION) for teachers have been discussed to take the place of previous teaching experience in other schools. According to one such plan, the candidate teacher would assist during the first year, without teaching; he would teach three-fourths of a regular load during the second year, under the guidance of the master teacher; and he would teach a full load under full supervision during the third year. Deffenbaugh and Zeigel reported in 1932 that about three and a half per cent of the elementary school teachers in the largest cities were new, as compared with approximately one-fifth in cities of less than 2,500 population. Similar proportions for high school teachers were from 4.6 per cent in large cities to more than a fourth in the smallest ones.

After assembling the written applications for positions and separating those which agree with the qualifications set up by the board for the position, the superintendent or personnel officer may use the interview, the written examination, or ratings on other instruments to establish the eligibility of the candidates. The interview, conducted by professional workers trained to employ it, is used to appraise the personality of the candidate, his educational philosophy, and professional outlook. The examination is not used as much as formerly, but is still the practice in a number of larger cities. The names of candidates who are eligible are sometimes set up in a ranked list for each type of position; but the current preference is for unranked lists of all the approved candidates. (See TEACHERS' EXAMINATIONS, NATIONAL; TEACHER RECRUITING; TEACHERS, APPOINTMENT OF.) A.V.O.

TEACHERS, STATUS OF. The present status of teachers in the United States is far better than in earlier days. Even today, however, teachers generally do not enjoy the recognition to which they are entitled by virtue of their professional studies and the importance of their work.

The standards for entrance to the teaching profession have risen steadily. Little more than a quarter of a century ago, the typical elementary school teacher had less than a high school education; today he or she has had more than three years of college work. The rate at which normal schools are converted into teachers colleges reflects the growing conviction that a college education should be the minimum preparation for teaching. An increasing number of school systems demand some graduate work of prospective teachers, especially of those who are interested in secondary school teaching. The emphasis on in-service education of teachers stems from the recognition of their great need for continuing professional studies. The interest which teachers take in professional activities is indicated to a degree, by the fact that approximately 20 per cent of the public school teachers in the United States are members of the National Education Association, while approximately 75 per cent are members of state teachers' associations.

The status of the teaching profession is reflected, too, in the salary the teacher receives. The average annual salary of classroom teachers in 1913 was a little more than \$500. This average increased to approximately \$1400 in 1930, decreased to \$1200 during the depression of the 1930's, and rose again to \$1400 in 1941. In general, medicine, law, dentistry, engineering, architecture, college teaching, social work, journalism, ministry, and library work rank above public school teaching in salary.

Though the teacher's initial appointment—and even his retention of his position—depend on the judgment of the superintendent and the local board of education as much as on the teacher's personal and professional qualifications, there is evidence of growing recognition of the status of the teacher as a member of a learned profession. State certification requirements set a minimum that even local favorites must meet for appointment as teachers. The National Teacher Examinations may serve as another attempt

to measure objectively some of the teachers' qualifications for appointment. The steady, though slow, spread of tenure legislation (See **TEACHERS' CONTRACTS**) helps assure the teacher that his continued appointment will depend on his professional competence and not on irrelevant considerations. The criteria which determine the teacher's appointment and reappointment, nevertheless, continue to reflect the local community's rather than the educator's conception of what a teacher should be, and many teachers continue to be selected with respect to such matters as their personal smoking habits, political and social views, racial, and religious background.

It is impossible to develop from the hundreds of thousands of public and private elementary and secondary school teachers employed by thousands of different school systems any clear-cut picture of the average teacher today that will be anything more than a statistical abstraction. How much significance should be attached to the facts disclosed by a survey that the median age of elementary school teachers is 27 years? That single men-teachers have rendered a median of four years of school service; single women, five years; married men, nine years; and married women, ten years? On the other hand, the educational sociologist finds it significant that more teachers come from families of median income of between \$2,000 and \$2,500 than from any other economic group. The teacher's family background may help explain why so many teachers experience difficulty in dealing with children who come from families where the standards of values and patterns of behavior are so different from those with which the teacher is familiar.

Despite many efforts to increase the number of men teachers, ranging from the eloquent plea of Phi Delta Kappa that "teaching is a man's job" to the practice, slowly disappearing, of paying higher salaries to men teachers than to women teachers, the overwhelming majority of American school teachers are women. The proportion of administrative and supervisory positions filled by men in the schools is much greater than is the proportion of classes that are taught by men. Whereas 61 per cent of the public elementary and secondary school teachers in 1870 were women, in March 1940, 79 per

cent were women. Because of comparatively low salaries in the schools and considerably higher pay in industrial work, the percentage of men teachers is descending to new lows. In 1940, 88 per cent of the kindergarten and elementary school teachers were women; approximately 70 per cent of the junior high school teachers were women; in reorganized high schools approximately 62 per cent of the teachers were women; and in regular and vocational high schools 56 per cent were women. There is a smaller percentage of women teachers in rural areas than in the urban systems, probably because of the prevalence of vocational-agricultural classes, which are usually conducted by men teachers.

In 1930, out of every 20 elementary school teachers, three or four were married women; three out of every 20 junior high school teachers were married women; and of every 20 senior high school teachers, about one or two were married women. Practices relative to the employment of married women teachers vary with the teacher's marital status, size of city, school level, and region. The pre-war trend in public sentiment has been against the employment of married women teachers. Rules and regulations of school boards regarding women teachers who marry while in service have been more favorable than in regard to married women applicants.

Those who favor the appointment or the retention of married women teachers hold that (1) a teacher whose marriage forces her to abandon her work is thereby removing from the classroom the benefits of her teaching experience, besides creating a feeling of instability among the students who have to adjust themselves to the replacing teacher, (2) the cost to the state of training new teachers is lessened by the retention of married teachers, (3) the policy encourages increased respect for wifehood and motherhood, and indirectly discourages spinsterhood among teachers, and (4) the student benefits by the clearer insight into and sympathy with adolescent problems, often evinced by the married woman teacher who is also a mother.

Conversely, those who oppose the appointment or retention of married women teachers object (1) to the competition of school duties with household duties for the teacher's time and attention, (2) to the fact that the situation may give rise to childless marriages,

(3) to the social problem created by employment being given to those whose marriage furnishes other means of support, rather than to the young unmarried teachers who may depend on teaching for their livelihood, and (4) to the lower salaries paid in certain teaching positions because of underbidding by married women.

The evidence from available studies of the relative efficiency of married and unmarried women teachers is inconclusive and contradictory; it offers little clue as to which policy with regard to the appointment of married teachers is the better. At present, the issue should be decided with reference to the basic professional and social considerations rather than on the evidence that has so far been adduced. TEACHERS UNION. The American Federation of Teachers, commonly called the Teachers Union, was first organized in April, 1916, and formally affiliated with the American Federation of Labor one month later. Delegates of eight local groups, representing 2,800 teachers, attended the first meeting. For the most part, the organization is composed of classroom teachers serving in public schools. Private school teachers may join if the institution in which they teach is not conducted for private gain or for religious purposes. Supervisors are eligible for membership only if the local accepting them has been in existence for a certain period of time.

Four years after its inception, the organization numbered 12,000 members and included 140 local organizations. Since then, membership has fluctuated, reaching a low point of approximately 3,000 in 1926, and a high of approximately 35,000 in 1941. Since 1941, membership has decreased. This loss of membership may be attributed in part to factionalism within the organization, culminating

in the expulsion of four of the largest locals from the American Federation of Teachers on the grounds of communist domination.

In general, the activities of the American Federation of Teachers center around the protection of salary schedules, pensions, tenure rights, and academic freedom. The organization has also shown great interest in social legislation, actively supporting the child labor amendment, federal aid to education, antidiscrimination measures, and local and national health and social security measures. Both the national and local organizations engage in active lobbying for legislation which they desire. In the political field, the American Federation of Teachers has advocated the formation of a farmer-labor party as the only way in which organized labor could attain its objectives.

The nature of the social and political programs which the Teachers Union has sponsored led to the charge that the organization is "radical." Its opponents insist that it seriously minimizes professional concerns in its eagerness to promote economic measures for the benefit of its members. The supporters of the Teachers Union, however, point to the discussions of professional problems at its public meetings as indicative of interest in professional as well as social and economic problems.

TEACHERS' WORKSHOP. A Teachers' Workshop is an experience-centered study undertaken by a group of mature persons. The group takes as its starting point the interests and needs of its members, and subgroups are formed to ensure a profitable interchange of opinion, knowledge, and experience. Consultants, rather than instructors, serve these groups, placing their specialized resources at their disposal both in group discussions and in exploration of individual problems and plans. The characteristics of this simple, informal, and functional organization are its flexibility and its relevance to specific tasks which the members wish to undertake more skillfully and with clearer vision after the workshop period.

The purpose is, therefore, not to provide

teachers with an opportunity to "earn credit," though credit has often been given by graduate institutions and by state and city departments of education. Experience has shown that teachers usually gain definite benefits, including an enlargement of knowledge, a broader outlook, new confidence, and a desire for further growth.

The workshop for teachers developed as a substitute for summer courses attended by teachers, which all too often required only a passive receptivity. It takes account, as courses attended could not do, of the variety of individual interests and the wide range of professional problems represented by a group of experienced teachers. Early experimentation was made under the auspices of a commission of the Progressive Education Association, which in 1936 brought together for consultation thirty-five teachers from a group of schools involved in a cooperative study of curriculum problems. In succeeding years other and larger groups were organized. Experience led to a revision of methods and the adoption of certain well-defined techniques. By 1940 fourteen colleges and universities had instituted summer programs utilizing these techniques and in later years many enterprises, with varying degrees of propriety, have been called "workshops." The workshop provides its members with information and expert professional direction, but its distinctive feature is that such assistance is relevant to the specific needs of the participants.

Many teachers need, not more knowledge primarily, but freedom to use what they know, confidence in adopting methods which others have found fruitful, assurance in attempting closer cooperation with colleagues. Such freedom and confidence is a usual product of the workshop, because each member finds he is valued, his problem is considered worth attention, his experience is taken as a starting-point for discussion, his growth is part of the purpose of the group. He brings with him an interest born of experience; he finds consultants and fellow-participants ready to relate that interest to theirs and to join him in the search for new ways of making it effective in professional and personal growth. Outstanding in evaluations of typical workshops by participants have been tributes to the help which they have found in conferences with staff members.

The individual member finds, in a well-conducted workshop, that his personal interests give him a place and a part in the work of a group of people whose activities he has a share in planning. These groups utilize the larger experience, expert knowledge, or leadership gifts of staff members ("consultants"), but do not become instruments serving the private purposes of the staff. Nor are they once and for all fixed in their form. A group may subdivide permanently or temporarily, or coalesce with other groups; it may follow one plan for a while and then adopt another to guide its discussions; or it may suspend meetings for a period of time. The democratic character of the group life, at once encouraging general participation and requiring subordination of individual preferences to group progress, has been generally acclaimed as a significant contribution to the growth of teachers in service, many of whom have known only an authoritarian pattern of professional organization.

One of the contributions of the workshop lies in its clear demonstration of the interrelationships which give meaning to traditional subject fields. Staff members are selected not only because of their competence in special fields, but also because they recognize and can interpret relationships.

The benefits of the workshop are found not only in the formal and planned activities and discussions, but in the day-by-day associations made possible when a group of people live together under conditions making for fellowship in work and play. Not least in value are the opportunities often provided for participation in arts and crafts. This activity provides release and reveals unsuspected talents, thus contributing to personal adjustment.

After several years of leadership in the organization of workshops, the Progressive Education Association in 1940 united with the Commission on Teacher Education of the American Council on Education in setting up a Workshop Advisory Service, which has counselled a large number of groups in their use of workshop techniques. This helped to save a significant movement from the dissipation of its achievements in ill-considered and inept imitations.

A word of caution is necessary. A workshop is not created by adopting the pattern of organization above described. Much de-

pends on the experience, judgment, and basic attitudes of those selected for the directing and consultant staff. They must, above all, appreciate and patiently use democratic procedures, yet give definite leadership. They must be interested in those they serve and demonstrate their friendly concern in a variety of ways. And those who enroll must be selected for that privilege so that no group has to contend with the liability of frivolous, unresponsive, egotistical or aggressive members. As far as possible, there should be advance assurance that those enrolled are persons likely to be able to make an active contribution, after the workshop, to the shaping of policy and the improvement of methods in the schools or colleges to which they will return.

TEACHING PRINCIPAL—See PRINCIPAL, SCHOOL.

TEMPER TANTRUMS. Temper tantrums really are cases of extreme negativism of an explosive type wherein a child often throws things, breaks or scratches furniture, screams, kicks, throws himself on the floor, bangs his head against the wall, or holds his breath.

These outbursts occur most frequently between 2 and 3½ years, but may appear as early as 14 or 15 months of age. Even the most violent tantrums do not last longer, however, than 4 to 5 minutes and some often less. As the child grows older the outbursts become fewer, but their after-effects (such as sulkiness and resentfulness) tend to persist longer.

Temper tantrums may result from the child's desire for attention or from having his activities thwarted. Furthermore, they may be symptoms of fatigue or of poor physical condition induced by colds, constipation, or enuresis. They may also be caused by jeal-

TEMPERAMENT

ousy of another child in the family, or may merely be the imitation of high strung and uncontrolled parents.

In dealing with temper tantrums it should be kept in mind that very few children (except heart cases) will injure themselves by these outbursts. Thus, it is best, in most instances, to ignore this behavior, leaving the child by himself until the tantrum is over and then, without comment, allowing him to rejoin the family group. Slapping, spanking, and scolding are ineffectual and only serve to aggravate the problem. Parents should be calm and self-controlled when handling these episodes, and should not demand meaningless apologies. It is essential, also, to see that the child does not gain what he wants, either directly or indirectly, by resorting to temper tantrums. F.K.M.

TEMPERAMENT. *Temperament* sometimes is, and sometimes is not, distinguished from personality. Allport, who endeavors to make the distinction, describes it as the "internal weather" in which personality develops." The four temperaments that the ancients distinguished—the sanguine, the melancholic, the choleric, and the phlegmatic—were attributed to the "humors" of the body. Humor and mood are still used synonymously with temperament except that they usually refer to a more temporary state, while temperament refers to a dispositional tendency. Both the temperaments the ancients distinguished and the wide variety of temperaments that have received names to date (e.g., irritability, boisterousness, dreaminess, moodiness, etc.), refer to a mode or style of behavior which may otherwise vary in every sort of manner and relate to all kinds of interests and values.

Temperament has always been recognized as having some relationship to the body and it is usually regarded as rooted in constitu-

tional factors and as largely hereditary in origin. Modern research has shown that temperament is intricately tied to body chemistry, so intricately that it is difficult to establish any one gland as determining a particular temperamental effect. It is only when there is serious glandular dysfunction that the resulting temperament can be moderately well predicted. Favorable modification of temperament is expected to result through promoting the normal functioning of the endocrine glands so that they serve to maintain the equilibrium of the body functions.

It must not be thought, however, that temperament is unmodifiable except by nutritional and medical treatment. It is true that infants in the first few months of life show differences in temperament by laughing or crying more readily, by greater irritability, fearfulness, or approachability. Though there is evidence to show that some of these traits of the first year persist to middle childhood and later, under some environmental conditions the traits are strengthened and under others they are diminished even to the point of disappearance. Timidity, apathy, moodiness, etc., may be counteracted by seeing that the child has certain favorable experiences, while optimism may be destroyed if life continues full of disappointments. While temperament may change less than other phases of the personality, its nonrigidity is evidenced by the fact that no individual displays a trait of temperament to the same degree in all situations. A "sunny" child is not equally sunny on every occasion, a slow-responding person is found to "fire-up" quickly under certain circumstances. There is no reason to believe that the provision of a type of environment which will tend to call forth temperament of a certain quality will not eventually change the threshold of the trait.

In a discussion of affective factors and learning, Prescott considers the probability that individual differences in temperament, such as emotional lability, may have an important and direct influence on the learning process. Unfortunately there is a complete lack of experimental data in this area.

TEMPERANCE EDUCATION. In the United States "temperance education" has generally referred to special instruction concerning the physiological effects of narcotics, especially alcohol. Narcotic drugs and tobacco also are involved, but usually to a lesser degree. Such instruction is required by law in physiology and hygiene instruction of public schools in most states, and has been for at least the past thirty years. For various reasons temperance education, even when required by law, has not had the enthusiastic support of many educators. These reasons include: 1. disrepute of the earlier temperance education because of its unscientific nature; 2. over-zealous efforts of reformers to make temperance education a means to promote temperance legislation; 3. introduction of national prohibition with resultant relaxing of all educational efforts in temperance; 4. constant propaganda of commercial interests through advertising of alcoholic beverages and tobacco; 5. failure properly to train teachers in teacher-education institutions so that they have adequate knowledge of the problem and enthusiasm for teaching temperance.

In the past two decades scientific knowledge about the physiological, psychological, and social effects of indulgence in alcoholic beverages, drugs, and tobacco has widened rapidly. The result is that there is a respectable body of fact that can be taught with reasonable assurance of its authenticity. Textbooks in health, hygiene, and physiology containing this information are now available for use throughout all school grades. Syllabi on alcohol, drugs, and tobacco have been prepared by many city and state school systems. However, what teaching is being done in this field is chiefly in the elementary schools, despite the fact that young people face their most difficult decisions regarding indulgence after they have left the elementary grades.

Several recent developments have led to a shift in emphasis in temperance education. First, the increasing importance of safety, especially in driving, has given added point to study of the use and effects of alcohol. Second, while not a new emphasis, the strong

desire among both boys and girls to be physically fit for competition in sports provides a basis for motivating temperance education. Third, recognition of the psychological fact that drinking and smoking are motivated by understandable desires has led to an increased concern for the alleviation of the motivating circumstances. This leads the student into the economic and social sources of drinking and smoking and takes the discussion out of the realm of reform and into the realm of intelligent social planning. Fourth, there has come an increased recognition of the fact that if there are understandable motives to drinking and smoking then the alleviation of the problem must entail adequate substitute means of expression. For example, "Allied Youth," an organization for high school pupils who pledge themselves to abstinence from the use of alcohol, arose as a means of giving social prestige to abstinence. There is social pressure to drink; there must be corresponding social advantages to abstaining—this is the thesis upon which this organization operates.

Where temperance education is being seriously promoted today the emphasis, then, is four-fold: first, presentation of scientific facts in classes in health, hygiene, and physiology; second, recognition of the social implications of the problem in social studies classes and in literature; third, careful effort to satisfy by harmless substitutes the desires from which indulgence arises; and fourth, recognition of social approval as one of the most powerful of incentives, with the attendant inclusion of this incentive in temperance education. Social approval may come through the leadership of teachers who already have prestige. Youth organizations can provide a sense of belonging for the youngster who does not want to indulge. A constructive program of physical and social activities in such organizations is no doubt one of the best incentives to temperance and abstinence.

TENURE. *Tenure* refers to employment on an unconditional or permanent basis, except as provided in the law which creates it. It is customary for tenure laws to provide for a probationary period of service of from one to five years, during which a teacher may

be dismissed at the close of any year by the school board without showing cause for its action. But after the probationary period, if the teacher is retained she may not be dismissed without cause. (See **TEACHERS' CONTRACTS**.)

Indefinite tenure refers to employment for an indefinite period, with no date specified for the expiration of the employment.

The average length of tenure differs much in various states and communities where studies have been made. The National Education Association, Research Division, in 1938 reported a positive relationship between the tenure of city superintendents and the existence of laws designed to safeguard the tenure of teachers. The same source reported, from a study of 936 state university teacher-training graduates, that at the end of the fifth year after graduation 52 per cent had taught all five years in the public schools. For the 52 per cent, the average tenure in one school system was three years. These teachers changed positions less frequently in states having statewide indefinite tenure than in others.

Overn traced the movements of 1,036 teachers for nine years after they commenced their initial teaching experience in Minnesota. Forty-six of them were teaching in Minnesota during the ninth year. The average tenure in all classes of schools in that state, for the 990 who were no longer teaching in the state, was 2.29 years for men and 2.67 years for women. In general, the movement of those teachers to other school districts seemed to carry with it some improvement in their status.

In Illinois in 1938 the average length of tenure in the same district was 13.5 years for Chicago teachers and 3.2 years for all others. It was progressively greater in larger communities in the state. Judd reported that the average length of service of 11,220 teachers in New York outside of New York City at the time of death, retirement, or withdrawal, was 17.6, 35.3, and 4.6 years, respectively.

In 1930, superintendents and teachers reported the causes of withdrawals from teaching in the one-room schools of Michigan. Frequent causes were: to attend college, to secure a better position, or to marry. Those of rural birth and rearing withdrew as frequently as the others.

Serious attempts have been made in recent tenure laws to protect the teachers from unjust dismissal. The Pennsylvania law, for example, prevents dismissals for political causes, according to Scott; but it does not help reduce the number of administrative units, eliminate schools that are too small, nor encourage the employment of professionally trained teachers in all schools. There would be an advantage in legislation which comprehended all such related issues when attempting to contribute to the solution of teacher-personnel problems. A.V.O.

TERM PAPER. The term paper, presumably based on considerable individual study and research, is a lengthy essay written by students as part of a course requirement. Although term papers are used occasionally in secondary schools and in the early college years, they are more common in courses designed for upper classmen at college and for graduate students.

The most frequent values claimed for the assignment of term papers are that they give able students an opportunity to do systematic, critical, and constructive work of their own under the instructor's guidance; that they supplement the students' knowledge of the field by wider reading and thinking and by greater practical handling of the material than is possible through daily assignments; and that they enable a student to explore more fully some phase of the course in which he has a special interest or which he is particularly well qualified to investigate, and which should not take up the time of the class as a whole.

On the other hand, instructors object to the time that must be spent in reading and commenting on these lengthy reports, and students complain that their preparation con-

sumes more time than they deserve. The inroads on the students' time may be so heavy that the legitimate demands of other courses are slighted. The topics are often far too ambitious for the students who are to do the research, with the result that much of the work is superficial. Moreover, instructors sometimes find that students merely paraphrase published material or that they recopy the term papers written by previous generations of students.

Extensive use has been made of various substitutes for the term paper because the task of writing, consuming time that often can be devoted more profitably to other phases of the assignment, sometimes detracts from the value of the assignment. What the substitute assignment is depends largely on the nature of the course, the composition of the class, and the special needs to be met by the assignment. Thus, if the assignment aims at introducing the student to bibliographic research, he may gain as much from the preparation of a carefully annotated bibliography as from the writing of a paper.

Where term papers are employed effectively, students are assured adequate guidance during the conduct of the research and the actual writing of the paper. They are helped to grasp the meaning of the various topics so that they may choose wisely the subject they are to explore. They are guided in their research so that they work most effectively. The students gain much from criticism of their outlines before they do the actual writing. A conference after the completed paper has been read by the instructor is also valuable. When this cannot be arranged, the student's paper is returned with a fairly complete analysis and criticism.

At some institutions, instructors who use term papers are expected to plan the day-by-day assignments so that students are not compelled to slight the reasonable demands made by other courses. The assignments are also planned so as to reduce the severity of peaks of work.

TERMAN, LEWIS MADISON(1877-).

Terman, one of America's foremost psychologists, was born January 15, 1877, in Johnson

County, Indiana. He received his B.A. (1902) and his M.A. (1903) degrees from Indiana University, and his Ph.D. degree (1905) from Clark University. From 1910 until 1942, when he retired, he was Professor of Psychology at Stanford University. He has been on the editorial board of numerous psychological publications, and in 1923 was president of the American Psychological Association. His contributions to education are noteworthy.

Terman's name is indissolubly linked with the revision of the Binet test. He was one of the first to realize the possibilities in this method of measuring intelligence, and the Stanford Revision of the Binet-Simon Scale, of which he was the author, has been the standard form in use in this country since 1917. In 1934 he published, with the collaboration of Maud A. Merrill, the new revised Stanford-Binet Scale.

Antedating his concern with the Binet test was Terman's interest in genius. After the first World War he secured a grant to make an initial and follow-up survey of one thousand gifted children in the State of California.

Terman has been interested, also, in problems of personal hygiene as they relate to the health of teachers and pupils and to the program of health work in schools.

Still another facet of interest in the early part of his career was the reading interests of children; with Lima he made an investigation in this field. The principal contributions in his later work are in the sphere of the relation between sex and personality, and factors contributing to marital happiness.

Terman contributed to the preparation of the Army Alpha Intelligence Scale, a group test used extensively in the Army during the first World War. He was impressed with the possibilities in group intelligence testing in schools and was on the committee responsible for the construction of the National Intelligence Tests. His own test—the Terman Group Test—has been widely used for many years at the secondary school level. P.M.S.

TEXTBOOKS. Investigations show that the textbook plays a prominent part in American education in determining both the content of instruction and, to a considerable extent, the teaching procedures, although changes in teaching procedures have not kept pace with the suggestions and provisions for new methods and techniques contained in many of the newer books. Teachers are often prone to continue old procedure even with the adoption of new textbooks.

Considering the dominant place of the text-

book in American education, we have been fortunate in that, for the most part, there has always been open competition in the preparation and production of textbooks, and that laws and regulations have fostered the selection of textbooks upon their merits. These conditions have stimulated publishers to use every means possible—investigations, experimental studies, try-out processes, etc.—to produce a superior product. Through frequent revisions and new editions textbooks are kept abreast of progress in knowledge and the best in educational thought. They are usually well made mechanically, and recent books are attractive in make-up and physical appearance.

On the other hand, textbooks may also retard changes in education. Since publishers are dependent on the market for the sale of a book, they try to please as many teachers as possible rather than take the risks involved in predicting which of the many trends in teaching will develop the greatest number of followers. Textbooks thus sometimes help perpetuate traditional methods and materials. For apparent reasons publishers are interested in books that have an appeal for teachers in as large a geographic area as possible. Textbooks are often, therefore, so general in appeal that they do not meet the specific needs of any given class. Although it is odd to object to the fact that textbooks are usually well bound, the fact remains that the physical life of a textbook sometimes outlives its usefulness. Many a student is studying his history and his science from books that were acceptable at the time of publication but are now obviously dated. When schools purchase the textbooks and distribute them to students free of charge, there is added reason for continuing to use a textbook beyond its period of greatest value, since it is cheaper to replace a few copies that have worn out than to purchase a complete set of new books.

Since the average beginning teacher in American schools lacks broad training, the modern textbook is a valuable asset for young teachers. Investigations show, however, that as the average teacher acquires experience, he gradually becomes independent of the textbook and relies more on his own judgment in selecting reference materials and collateral reading and in organizing the subject matter. A good modern textbook is especially

valuable in school today because: (1) It furnishes subject matter which the teacher may use as a basis for his own course planning. Most of our texts are based upon years of experience and experimental research, and supplementary material can be supplied according to class needs. (2) It furnishes supplementary problems and exercises as well as supplementary devices, such as check-lists, tests, and suggested activities for pupils. (3) It furnishes a good plan of organization which may be used for planning reviews and for helping pupils in organizing the material of a course. (4) It is a good source of reference to be used with topical outlines or laboratory problems.

Although the so-called textbook method of teaching has fallen into disrepute because of the way the textbook had been used in the old question and answer procedure, it can be used advantageously with: (1) the recitation-discussion procedure, (2) the problem-method procedure, (3) the laboratory procedure, and (4) the unit plan technique. The textbook may be used for the assignment of topics for study or it may be used as a reference for data or other helps. Many teachers are making use of textbooks in teaching pupils how to study and to use books, since all pupils are supplied with the same material for class use.

The textbook plays so important a role in school work that it is essential for teachers and administrators to have a sound basis for evaluating the books to be selected. The factors usually considered are: (1) authors, including their training, experience, and philosophy; (2) nature and organization of content, including its reliability, suitability to objectives, adaptability of organization of content to desired teaching procedures, and adaptability to pupil needs; (3) instructional aids for using the textbook; and (4) mechanical features, including the typography and format. The use of a score card for the analysis and appraisal of textbooks has been advocated, but there is considerable disagreement concerning the value and reliability of such devices; however, their use often has resulted in more careful analysis and better data for comparative purposes. There are few published score cards that have been accepted as authoritative.

The units for textbook adoption are usually

the local district, the county, or the state. Twenty-five states make the state the unit for uniform adoption, but some exceptions are made for certain cities or districts. The purpose of larger units is to secure greater uniformity and to reduce costs. For the most part state uniformity is confined to the South and the Far West, while the New England, Great Lakes, and prairie states have local or county adoptions. There are many objections to state uniformity because of its inflexibility and lack of provision for local needs, the danger of incompetence in textbook selection, and the possible influence of bribery or political pressures in the selection of textbooks.

California and Kansas publish part or all of their textbooks for elementary and secondary schools. Educators generally are opposed to this practice because of the danger of undesirable administrative control over the content of textbooks and the stifling of progress. Moreover, state publication has not reduced costs. Most states have laws protecting the adopting units from unfair practices, and competition usually has kept prices low.

The adopting authority usually varies according to the unit of adoption. In the forty-eight states and the District of Columbia, textbooks are selected as follows: (1) in seven states by a textbook commission or committee; (2) in eight of the state board of education; (3) in eleven by the local school board working with one of the preceding; (4) in six, county and local boards have joint jurisdiction, and (5) in seventeen, the local school boards make the selections. Usually the selection by school boards is made upon the recommendation of the superintendent of schools or of a committee of teachers or others appointed for the purpose.

In twenty-seven states and the District of Columbia provision for free textbooks is mandatory. In twenty others provision is optional for the elementary schools, ten of the twenty including the secondary schools. All states provide free textbooks for dependent and indigent children. A few states provide for the purchase and rental of textbooks to pupils at a fee to cover cost of books and administration.

TEXTILE SCHOOLS. Most schools and departments of home economics (*q.v.*) in junior and senior high schools and at the university level give instruction in clothing. Textiles are studied and used in making garments. In a few centers, for example in New York City, there are high schools of textile trades. In such schools various skilled textile trades are taught—trades such as textile designing, loom fixing, and dyeing.

There are also textile schools of post high school grade where textile trades and professions are taught, as well as cost accounting, organization and management of textile plants, and other advanced courses. Some of the post high school textile schools are of college or university grade. They offer four-year curriculums in textiles, and grant degrees to those who successfully complete them. Clemson College, South Carolina, and the North Carolina State College, Raleigh, North Carolina, are examples of such institutions.

F.T.S.

THESIS. The terms *thesis* and *dissertation* frequently have been used interchangeably to indicate the relatively extensive piece of writing included as part of the requirements for completion of the course leading to a graduate degree. Preferred usage, however, tends toward *thesis* as the label for the Master's project, which is expected to show ability to think independently and to carry forward a carefully delimited problem to its logical or scientific solution, although the Master's thesis need not be a fundamentally original piece of research. For purposes of differentiation, *dissertation* may well be reserved to identify the Doctor's investigational project, which should represent original research and independent thinking, adequate methods, logical and sound conclusions, good literary form, and a contribution to knowledge worthy of publication.

THINKING. Constructive thinking, defined as the formulation of ideas which redirect behavior, is a process in which materials and activities of all kinds, either actual or symbolic, are used as practical tools to resolve a problematic situation where ambiguity and uncertainty have made the next step indeterminate. Such a definition is opposed to the concept of thinking as mere mental activity to be engaged in for its own sake, or as a stream of sequential ideas detached from pragmatic consequences and human purposes.

In a classic description of reflective thinking, Dewey (*q.v.*) has analyzed the various processes involved in the complete act of thought. In the first place, thinking arises out of doubt and is an essential activity when progress toward the goal is blocked. Blocking may be owing either to a lack or an excess of paths to the goal, or to a feeling of doubt as to the adequacy of the path one already has in mind. When the perplexity arises from a lack of means by which the goal may be attained, the various aspects of the situation must be scrutinized until a possible plan for reaching the goal has been constructed. The goal, as well as past experience with similar situations, will guide one to pertinent and usable data. Once suggestions for further action are in mind, the reflective thinker proceeds to gauge their adequacy, to determine their consequences if acted upon, and to select the one most promising way in the light of the total situation, including all the consequences that have been plotted. The testing of the various hypotheses is done in terms of both reflection and of such ordered experimentation as is possible. On some occasions, putting a plan into full operation is the only empirical test possible. In any event, whether there has been preliminary experimentation or not, thinking should not be brought to a close until the plan has been put into operation and the manner in which it is actually working out is seen. Evaluation of these ongoing results is needed both to make sure that changes are instituted as they are seen to better the future outcomes, and to gain techniques and ideas for the solution of other problems which are now envisaged.

The period during which suggestions are developed, elaborated, and evaluated is the time when there is a great deal of inference-making. Inference-making is the process of

"arriving at an idea of what is absent on the basis of what is at hand." In situations in which the perplexity does not arise because of the need to construct or determine upon a means to a goal, but rather from the desire to understand better the nature of some object, the inference-making takes on largely an *explanatory* character. The reasoning processes in both types of doubtful situation, however, are similar. The desire to gain the understanding leads one to scrutiny of the present situation and to the recollection of relevant data necessary for the *construction* of the explanation. The explanation must be tested or *proved* and such testing must be also of an empirical nature. It must be a test *in fact*. Sometimes the test necessitates only further observation; sometimes it necessitates the manipulation of conditions to determine whether the cause and effect relationship which one has inferred is a true one. Intellectual curiosity, if it is not to be sterile, must have a connection with action. Though the action may on many occasions be imagined rather than overt, it must at all times be a trying out of the idea "to determine its agreement with the requirements of the situation."

On the other hand, the construction and carrying out of a plan for reaching an objective must contain also the feature of intellectual curiosity. The interest must be sufficiently theoretic and impartial to allow new and doubtful-appearing ideas to be put to the test. Action with poverty of thought and thought with poverty of action are equally inadequate. Both action and thought need a base of experience if they are to proceed effectively.

From the above description it is easily seen that thinking can be done in an excellent, mediocre, or poor fashion. It is a skill possible of development, and schools are setting up the improvement of the ability to think as one of their objectives. One of the first things of which the school must become aware is the intimate relation of language and thinking and the infinite creative possibilities as well as the multitude of dangers that arise out of this relationship. The development of language is essential for the development of complex forms of thinking, because words become signs of more or less specific meanings which can thus be handled easily and applied in different contexts. The concrete reference of particular words to specific ob-

jects and actions is clearly seen in the primitive tribe's vocabulary and in the young child's naming of persons, things, and activities. Because of the fact, however, that an immature child today encounters in a modern, civilized society a very extensive vocabulary containing a large proportion of abstract words, he may be confused in his thinking by the multitude of concepts represented and by the lack of concrete reference for many words that he hears. Especially dangerous is the situation where adults in the home or school insist upon verbal learning without making the meanings clear and significant through experience appropriate to the child's developmental status.

Training in thinking, according to the description of the process outlined above, involves the encountering and solving of problems that necessitate modification of action on an empirical as well as on a verbal plane. No area of subject matter, such as mathematics or language, has primary value for training in thinking. From early childhood through maturity the individual should be led into a variety of problems as wide and deep as his abilities and interests, and the needs of his society require. Through these experiences he must learn when to stop to think, how long to pursue the development of suggestions in different cases, how to choose objectives and use them in evaluating his own progress, and how to test the validity of the conclusions which he reaches.

A prominent danger to be avoided in constructive thinking is prejudice or prejudgment stemming from emotional attitudes. While thinking that is creative cannot be a cold, mechanical process moving by iron-bound rules but must be an exciting and flexible pursuit of vital interests, the thinker must not exclude relevant evidences or suggestions because of personal likes and dislikes. The development of emotional stability and of social attitudes is essential in the training of thinking. Fortunately, these several aspects of development — intellectual, emotional, and social—are closely related, for thinking is a social process, as language is a social product. An individual thinks effectively when he combines reflection with action and accepts suggestions and criticisms from his fellows without emotional upset. Thus, the child who is to become a mature thinker needs early to begin facing problems

as a member of a cooperating group having common interests and achieving common goals. In such a social context he may acquire attitudes that will serve him throughout life in solving individual problems as well as those problems which he shares with others. Under these conditions thinking becomes also a guide to social, ethical conduct and an instrument in choosing objectives appropriate to human development. Consequently, thinking on the part of every individual is essential to the democratic way of life, while the development of the desire to base action upon thought and the improvement of the skill with which problems are thought through become fundamental objectives of the democratic school. THORNDIKE, EDWARD LEE (1874—). Edward Lee Thorndike is one of America's eminent scientists in the fields of education and psychology. He was born in Williamsburg, Massachusetts, on August 31, 1874. He received his A.B. degree (1895) from Wesleyan University, another A.B. (1896) and his A.M. (1897) from Harvard University, and his Ph.D. (1898) from Columbia University. From 1904 until 1940, when he retired, he was Professor of Education at Teachers College, Columbia University. He holds many honorary degrees and has been president of several learned societies in this country.

Primarily a man of science, Thorndike's career, particularly in later years, has been devoted to research in the field of educational psychology. Probably he is best known for his investigations in the theory of learning,

having been the first to formulate the "law of effect," generally recognized as a basic law of learning. He has also made substantial contributions to the theory of psychological measurement, and is the author of several tests, notably the Thorndike Intelligence Examination for High School Graduates, and the Intelligence Scale CAVD, a carefully standardized power test running in a series of sections from the easiest to the most difficult levels. He was one of the first to use statistics in the study of mass data in psychological factors and educational outcomes.

Among Thorndike's contributions is the *Teacher's Word Book*, an inventory of the ten thousand (later extended to twenty thousand) most commonly used words in the English language. On the basis of this count he wrote the *Thorndike Century Junior Dictionary* and later the *Thorndike Century Senior Dictionary*. He has made noteworthy studies of the teaching of arithmetic and algebra, of the psychology of reading, of the effect of ventilation on efficiency, of the disciplinary value of school subjects, of adult learning, and of the factors associated with the cultural levels of cities. His three-volume work, *Educational Psychology*, was for many years both a pioneer and a standard work in this field. P.M.S.

THRIFT EDUCATION. Thrift education in the schools has commonly been thought to comprise training in saving money. This training has usually been done through school banks and savings funds. Such banks were first organized more than a hundred years ago in European schools and were wide-

ly popular there before their introduction into American schools. The savings Division of the American Bankers Association has actively promoted school banks. The common objection to such savings plans—that they place children from needy homes at an undesirable disadvantage—has been met in some schools by canvassing the community for odd-job opportunities for these children so that they may earn money. Some criticism of savings plans in the schools comes from the fact that the money which the children save represents not their own thrift but money received from their parents.

Thrift has also received emphasis in school readers, in social studies units, and in the content of classes in orientation, personal adjustment, and home economics. This emphasis usually broadens the concept of thrift to include conservation of time, energy, materials, school and community property, and natural resources. "Thrift" thus becomes more than a matter of seeking personal economic security and becomes a matter of social planning. Also, thrift so taught provides many opportunities for developing attitudes of honesty, responsibility, and unselfishness.

War time conditions have stimulated this broader concern for "thrift" education because of the greatly increased earnings in the face of a steadily diminishing supply of consumer goods. Recognition of the desperate need for conservation is suggested by the warning that, "You will either teach about thrift in your schools, or else you will wind up with a dictator making the decisions arbitrarily about saving that intelligent and informed people would otherwise have made for themselves."

An element of thrift education of recent origin in the school curriculum is found in the increasing attention to consumer education (*q.v.*). Consumer education provides for the practice of thrift through wise buying. This instruction has been largely limited to girls, especially those taking home economics courses. However, courses in consumer economics in secondary schools and colleges have tended to encourage boys into this important field of thrift education. G.E.H.

THYROID GLAND — See ENDOCRINE GLANDS.

TICS. Involuntary movements performed over and over, and confined to small groups of muscles. They may be functional or may be caused by some irritation arising from a structural defect. Thus, blinking of the eyes or twitching of the mouth may be associated with emotional conflict, while putting fingers into eyes or ears may persist after the irritation which originally caused these habits has disappeared.

Because a tic is an involuntary movement, obviously it cannot be controlled by the child. Nevertheless, parents sometimes nag or ridicule children afflicted with tics because they believe the trouble to be a habit, which can be eliminated if the individual makes an effort to do so. On the contrary, the emotional tension created in the child by parental censure or by his resentment at being punished unjustly may increase the difficulty of correcting the tic. The emotional or organic basis for the tic suggests the reason for the failure of any attempt to cure it directly rather than by removing its emotional or physical cause.

Ordinarily the child with a tic requires professional care far beyond that which can be given by an interested teacher. About all a sympathetic teacher can do to help the child who is thus afflicted is to surround him with a wholesome emotional atmosphere. The teacher should take care, of course, not to add to the child's tension by overemphasizing competition and rivalry or by making him feel inadequate. R.V.M.

TIME ALLOTMENT OF SCHOOL SUBJECTS. For a long time it has been the custom, particularly in elementary schools, to designate the amount of time which should be allotted to the various school subjects in an arbitrary manner. Attempts have been made to determine scientifically the amount of time to spend on various subjects, but up

TIME ALLOTMENT OF SCHOOL SUBJECTS

to 1943 no general standards had been agreed upon.

The following is typical of what is now required in many states:

PROGRAM OF STUDIES FOR SCHOOLS IN INDIANA*

*(Administrative Handbook for Indiana Schools, State Department of Public Instruction, Bulletin, No. 100, 1937).

A. PROGRAM OF STUDIES FOR GRADES 1-6

1. Language Arts—Reading, Oral and Written Expression, Writing and Spelling.
2. Social Studies—History, Civics and Social Geography.
3. Mathematics.
4. Elementary Science—Nature Study, Physical Geography.
5. Fine Arts—Music and Art.
6. Health, Safety and Physical Education.
7. Practical Arts.

The following are the suggested time allotments for the subject groups named above. These allotments include time spent in class instruction and study.

(1) Teachers will note that the time allotment is suggested for an entire week. This makes possible an arrangement of the program wherein certain subjects, for example: language arts, mathematics, social studies, fine arts, safety, health and physical education should appear in the program daily, while the elementary science and industrial arts might appear only at regular intervals.

Some teachers may want to work continuously upon certain units, for example: in elementary science, health, safety, or other subjects where the time allotment is small. This will be satisfactorily provided in the course of the grade period or semester, the approximate suggested time allotment is given to the various subject groups.

(2) Intermissions referred to in the time allotment have reference to the rest periods usually in the middle of the morning and afternoon sessions. These should come daily. In the case of primary grades, it may be desirable to have rest periods more often and for a shorter period. Teachers in the primary grades in consolidated schools where the regular school day is considerably longer than that usually assigned to the primary grades, should make the adjustment necessary to their grades by the use of rest periods, play periods, etc.

SUBJECT GROUP	Grade I Minutes per Week	Grade II Minutes per Week	Grade III Minutes per Week	Grade IV Minutes per Week	Grade V Minutes per Week	Grade VI Minutes per Week
Language Arts	680	620	670	575	550	550
Social Studies	50	50	100	200	300	300
Mathematics	†40	100	150	175	200	200
Elementary Science	35	35	35	35	40	40
Fine Arts	50	150	150	150	150	150
Safety, Health and Physical Education	120	120	120	140	160	160
Practical Arts	25	25	50	50	50	50
Intermission	150	150	150	150	150	150
Unassigned	100	100	75	25	50	50
Total for week	1,350	1,350	1,500	1,500	1,650	1,650

The length of the school day for the various grades can be found by dividing the suggested number of minutes per week by 5.

†The teacher should see the mathematics course of study for this grade for suggestions. Very little formal time, if any, should be spent in the first semester, and the time spent on mathematics in the second semester should be less formal than that spent on the subject in later grades. The mathematics instruction should grow out of the need and the desire of the child as he meets problems which call for the use of the operations suggested in the course of study.

(3) The unassigned time is meant for individual instruction, remedial and adjustment work necessary in every school.

(4) It is suggested that the opening exercise period, common in many of our schools, be purposeful in its nature to the point where it will contribute to one or more of the subject groups.

The exponents of *Progressive Education* (*q.v.*) do not uphold the time allotment of school subjects as prescribed above. They hold that a good curriculum for elementary school children centers around large enterprises and undertakings which permeate all aspects of school experience, giving meaning and significance to the many specific activities. Long periods for flexible work must be available. Exact time schedules with short periods, necessary when several teachers share the teaching of one child, defeat the effective development of such experiences. This problem of time allotment is tied very closely to the question of departmentalization. The progressives are certain that the only really satisfactory way to develop large central experiences and to have them permeate the entire curriculum, or at least most aspects of the curriculum, is to have the major responsibility for the school day of the child centered with a single teacher. (See *ACTIVITY PROGRAM*.)

The present trend is toward a compromise position between the traditional plan and the idea presented by the progressives. (See also *PROGRAM, DAILY* and *SCHEDULE, DAILY*.)

O.G.J.

TIME SAMPLING TECHNIQUE—See *CHILD PSYCHOLOGY*.

TOPOLOGICAL PSYCHOLOGY—See *PSYCHOLOGY, SCHOOLS OF*.

TORTIOUS LIABILITY—See *LIABILITY*.

TOUCH READING. This phrase refers to the process of securing meanings through embossed symbols through the sense of touch. This is usually done through the fingertips; though cases have been reported of an armless soldier reading with the nose. Various kinds of embossed symbols have been used; these are known as Roman letter, Moon types, American Braille, English Braille, and New York Point.

Braille is a system of reading by means of raised dots, devised for the blind by Louis Braille. The method of communication by means of raised dots came originally from the secret signal system of the French Army. When Louis Braille went blind his friend, Barbier, a cryptographer in the intelligence service, thought of using this secret code for communication with his friend.

Louis Braille subsequently modified and improved the code for the use of the blind. There are several different grades of Braille, graded according to difficulty. In Braille Grade 1, all the words are completely spelled out. Grade 1½ has 44 word abbreviations or contractions. Standard English Braille (Grade 2) has 185 contractions. Grade 3 is still further contracted. Numerous rules of syllabification and punctuation govern written Braille. M.E.F.

TOWNER-SHEPPARD ACT. The Towner-Sheppard Maternity Hygiene Act of Nov. 23, 1921 (42 STAT. 224, 42 U. S. C. 161) provided Federal appropriations for a period of five years to be apportioned among the states for the purpose of cooperation to reduce maternal and infant mortality and to protect the health of mothers and infants. The Supreme Court of the United States refused to sustain an attack upon the statute as being unconstitutional. *Massachusetts v. Mellon* (1923), 262 U. S. 447, 43 Sup. Ct. 597.

The Act was extended to cover Hawaii on March 10, 1924 (43 STAT. 17) but was repealed on January 22, 1927 (44 STAT. 1024) as of June 30, 1929.

Many educators hailed the passage of the Towner-Sheppard Act as an indication of federal support for more nearly adequate programs of preparental education, parental education, and preschool education (*qq.v.*). Although the Act was not in force long enough to exert any lasting influence on education, it encouraged the continuation of attempts at gaining federal aid for educational and health work with mothers and young children.

It is important to note that the Social Security Act of 1935, Title V, Part 1 (49 STAT. 629-31), as amended by 53 STAT. 1380-1) provides Federal grants-in-aid "for the purpose of enabling each state to extend and improve . . . services for promoting the health of mothers and children". H.N.R.

TOWNSHIP BOARD OF EDUCATION

—See BOARD OF EDUCATION, TOWNSHIP.

TOYS, EDUCATIONAL USES OF.

Though used by the child primarily for play and enjoyment, toys may at the same time aid in motor and manual development, as well as in mental, emotional and social growth. To be able to aid in such development, toys must be such as to demand growing skill or imagination on the part of the user. The toy which needs merely to be wound to do its tricks has little educational value and the same is true of the game where the moves are decided by the throwing of dice or the spin of a dial. Simple toys which lend themselves to a variety of games requiring different degrees of skill are good in that the child can always use them at his particular level of ability even though that ability is continually increasing. Push and pull wheel toys, balls, marbles, skipping ropes, tricycles and other such familiar media for muscular and manual activity retain their popularity year after year because the child can continually aim at more difficult skills in using them. Toys which help develop ideas of size, shape, weight, color and number are helpful for the young child. In this area there are boxes of different sizes which fit into one another if properly arranged, rings of different sizes to balance on a peg, shapes to fit into a form board, etc. For imaginative play, some equipment which the child can himself structure, such as blocks and boards and wheels and pegs, is necessary. This, supplemented by ready-made accessory toys such as dolls, animals, furniture, dishes, small trains, automobiles, boats and planes, will help the child play at events which actually happen in his environment until he better understands them. For older children, the more elaborate mechanical construction toys, as well as the model building sets of ships and planes are good. Many of these, however, require a degree of manual dexterity far beyond the ability of the children for whom they are usually bought. Some toys should be adequate for solitary play so that the child learns to get along by himself. Others should be adaptable to two or more players so that the child may learn how to get along with others, to take turns, and to keep to the rules of a game. Playing with

others also gives the child a chance to learn from others and so to improve his skill, knowledge and imagination. (See PLAY.)

Failure to derive the optimum educational value from the use of toys often results from the adults' poor choice of toys to be purchased for the child. To most parents, the toy represents merely a reward to be given to the child when he behaves well, or a gift that helps celebrate his birthday and Christmas. Furthermore, the choice of the toys to be bought reflects the adults' opinion of what the child would like to have, or even the child's actual interests, but rarely does it represent a considered evaluation of the child's needs and of the contribution which toys can make to help meet these needs.

When toys are selected wisely they are in harmony with the child's present interests, but they also help develop the child in areas and in traits in which further encouragement is needed. Thus, the child who tends to play by himself and to avoid the company of other children may be helped by being given toys that invite participation by a small group. Similarly, the youngster whose play activities are largely of the sedentary, indoor type, may need athletic toys appropriate for his age, such as a tricycle for the young child or a bicycle for the older one.

Since the parents rather than the teachers so often are the ones to determine the extent to which toys are used effectively, the use of toys as aids to child development is often an appropriate topic for discussion at parents' association meetings and in child study groups.

TRAFFIC REGULATION, SCHOOL.

There are included under this topic two phases of traffic regulation: (1) regulation of pupil traffic within the school building and (2) regulation of pedestrian and vehicular traffic to and from school.

In regulating traffic within the school building the school administrator is governed largely by the size and construction of his school building with respect to the number of floors, sizes and locations of classrooms; width of corridors; number and location of stairways; and the like. He should plan his class schedule in terms of these relatively fixed factors. He should, if the location of stairways leading from one floor to another permits, use one-way traffic, having pupils move either up or down on a given stairway. He should avoid as much as possible a cross flow of traffic in corridors. If class rooms have two exits, he should provide for one-way traffic at each of these points. Minor rules and regulations concerning movement of pupils at class change depend upon the individual administrator, his faculty, and his school plant.

A special type of traffic regulation is needed for special types of pupil movement such as fire drills, air-raid drills, and the like. At these times safe and efficient speed and utmost cooperation are at a premium.

Traffic to and from school may involve transportation of pupils by busses, pupils' use of bicycles, pupil traffic in crossing streets, and pupils' use of sidewalks. Most school administrators make use of student patrols in regulating pupil pedestrian traffic at street crossings, in loading and unloading school busses, and for other purposes where extra safety precautions are needed. TRAINING, TRANSFER OF — See TRANSFER OF LEARNING.

TRAINING SCHOOL FOR TEACHERS —See NORMAL SCHOOL; TEACHERS COLLEGE.

TRAIT. The observable consistency of behavior displayed to a greater or lesser degree by individuals both young and old has led to the concept of traits as generalized, neuropsychic systems which dispose the individual to act in certain similar ways in situations which have different specific stimuli. Kindness, acting upon reflection, preferring the old to the new, fearfulness that anything undertaken will turn out to be a failure, are a few of the multitude of traits which have been distinguished. It is seen that the specific way of acting may differ from situation to situation, even though the mode of behavior is sufficiently similar and distinctive to have the same trait-name, for example "dishonest," applied to it.

The erroneous assumption is sometimes made that personality traits are determined by specific inheritance and are separable aspects of the personality. That traits are a function of the environment, particularly the social environment, can be seen by the changes in personality that take place when the environment is radically altered. That traits are not separable aspects of the personality functioning in isolation from each other can be seen in situations where two or more such predispositions come into contact, necessitating a mode of behavior that is a display neither of one nor the other but of some integration of both. All analyses and testing of traits of personality need to be safeguarded by recognition of the unity of the personality, the interrelation of traits, their modifiability, and the inseparable action of inherited potentialities and social environment in the development of personality traits. While teachers are responsible for understanding the present traits of each pupil, they also have the opportunity to modify them substantially, since traits are permanent only to a degree, a degree which differs from trait to trait and from individual to individual.

TRAIT PROFILE—See PROFILE GRAPH.

TRANSFER OF LEARNING. This article has been titled transfer of learning rather than transfer of training since the latter term usually connotes a specific hypothesis of how transfer takes place. Since it is self-evident

that we do not meet new situations as if we had had no dealings with previous ones, the problem of transfer is not whether transfer takes place but to what extent and in what manner past learnings or experiences transfer to new situations to help or hinder us in solving them, and further, in what ways learning can be guided so that the maximum of positive transfer and the minimum of negative transfer may occur.

The popularity of the term transfer of training stemmed from its identification with the theory of formal discipline which for a long time was the accepted explanation as to how transfer can be made to take place. While the theory of formal discipline has now lost its prestige as a theory, the educational procedures which stemmed from it are still being practised. To understand the theory of formal discipline one must understand the *faculty psychology* upon which it was based. According to this psychology, the mind is made up of a number of powers or faculties such as the faculty of will, of feeling, of memory, of reasoning, etc. Some faculty psychologists thought of these powers as regions of the brain (compare with phrenology); others assigned to them no such specific physiological counterpart. Both groups, however, conceived that these faculties or capacities developed in much the same way that muscles develop. Muscles grow more able to do work such as pushing, and pulling, and lifting if they have already been exercised in pushing and pulling and lifting. The fact that new objects are to be lifted will not interfere with the ability to lift. The senses, it was argued, also develop through exercise. Keeness of observation and of hearing improve as the individual practises observing small details and listening to faint sounds. By analogy, it was claimed that the faculties of the mind, such as memory and reasoning, increase their functional ability when they have received exercise. These abilities were thought of as general abilities which could operate equally well on any type of material no matter what kind of material had been involved in previous memorizing and reasoning. The important thing was to discipline or train or exercise each of the faculties. The content of what was studied need not be useful in itself. It was believed that memory could be trained by memorizing

nonsense syllables and that reasoning could be disciplined by following the logic of any well set forth explanation. The school curriculum need therefore contain only a few subjects as long as these subjects provided exercise for the various faculties. The theory of formal discipline did not specify which subjects were most suitable. However, since Latin, Greek and mathematics formed the traditional curriculum of the time, these subjects were put forward as being the best subjects upon which the mind could be trained. In many a school, the amount of Latin and Geometry which is required of every student is not enough to lead to a degree of mastery which will enable the learning to be of some use. One must infer, therefore, that these schools still believe that reasoning in geometry will equip a person to reason in political affairs. "Memory courses" are still being advertised and sold, and probably the majority of our population still believes that the best way to train the will is to do or to be made to do unpleasant tasks. School people praised such subjects as Latin not only because the grammar of the Latin language was a logical one and therefore its study would sharpen reasoning powers but also because it was difficult and disliked by many students and therefore they would have an opportunity to exercise their will in applying themselves to it. Even today one hears prominent persons voice the belief that had Latin been a compulsory subject in our high schools, the American people would engage in their activities with more endurance and would be better able to reason about war and post-war policies.

The doctrine of formal discipline has been attacked from several fronts. Dewey's classical statement that effort follows interest pointed to a new criterion for selecting curriculum content and became a foundational principle in the practice of *progressive education* (*q.v.*). Many illustrations from life could be drawn upon to contradict the theory of mental faculties which improved in general. There were scientists who had a prodigious memory for the facts of their science but who could not remember the names of their neighbors; handwriting experts who could distinguish forgeries but were at a loss to follow a man's trail through the woods; bookkeepers who were painstakingly neat in

their account books but who wrote letters their friends could barely make out; mathematicians who could very quickly detect the fallacy in a false mathematical solution but who were easily influenced by all kinds of advertising propaganda. Illustrations from life, however, could always be countered with other illustrations. Sceptics of the theory of formal discipline therefore began to put it to empirical test.

Several ways of testing were used. In cases where subjects were practised in a simple task (e. g. the crossing out of every *a* and *s* on a printed page or the memorization of nonsense syllables) and were then given a new but similar task to perform (e. g. the crossing out of every *e* and *t*, or the memorization of poetry) ability in which was compared with the ability of a control, unpractised group, it was found that in some cases there was considerable transfer, in some cases little transfer, in some cases no transfer, while in some there was negative transfer, the first task seemingly interfering with the ability to do the second. Another method of investigating transfer is to compare the effects of classroom teaching of the various subjects. Thorndike gave high school students who were following different courses of study tests of reasoning at the beginning of a school year and again at the end. Improvement in the general ability to think as measured by Thorndike's tests was no greater for students who had pursued one course of study than for students who had pursued another. There were many individual differences, however, and students of high general intelligence gained more than students of low intelligence, no matter what subjects they had studied.

Since the many experiments undertaken to test the theory of transfer showed that transfer did take place to some extent, psychologists felt called upon to construct a hypothesis to replace the theory of formal discipline which was not confirmed by the facts. The theory of identical elements was proposed, chiefly by Thorndike. This theory asserted that mental performances are facilitated by previous mental performances only when both instances involve "identical elements." These elements may be common word roots as in Latin and English, overlapping items of information as in history and literature, or the same basic skills as are found in both

arithmetic and algebra. Beside identical elements of common content or instrumental skills, the term was extended to cover common "reactions" evoked by different learning situations which were likely to be similar, however, in at least some inconspicuous feature or element. Thus habits of work, attitudes of appreciation, and language terms were said to be identical elements through which what was learned in one instance became available for use in a second.

The principle that there must be some common feature between the old situation and the new for transfer to take place is still held as foundational. The emphasis on elements, on identity, and on the neural theory which Thorndike built up to accompany this explanation of transfer has been largely discarded. It has been pointed out that identity need not be present, similarity is sufficient. Objective equivalence, moreover, is not sufficient. The similarity must be seen by the learner. Identical elements embodied in different situations may not appear as identical. On the other hand, objectively different things may because of some attitude or purpose of the learner assume sufficient similarity for transfer of learning to take place.

Studies in *cross-education* attacked the theory of identical elements because it specified certain "synaptic" junctions between nerve cells to be the locus of practice effects. Experiments were undertaken to discover if the results of training one body member (e. g. the right hand) would transfer to other body members (e. g. the left hand) or whether the person would be limited by the particular synapses involved in the use of the trained member. Such studies have in general shown that cross-education does take place. Emert found that right-handed subjects who had already learned to trace a pattern with the right hand by the mirror drawing method did better on the first tracing they then made with their left hand than they had done on the first right-handed tracing. Bray found that there could be cross-education from hand to foot and vice versa. Lashley trained rats to make brightness discriminations with one eye while the other was blindfolded and found that perfect discrimination continued when the blindfold was changed to the opposite eye. Lashley also found that monkeys who had learned to open a latch with one

hand while the other had been temporarily paralyzed were quite able to perform successfully with the paralyzed hand when it had recovered and the trained hand was paralyzed. Gestalt psychologists are particularly interested in these studies on cross-education, claiming that they prove that learning and transfer of learning occur in terms of the gaining of insights rather than in terms of the training of specific parts of the brain or of the rest of the body, and that it is the total neuromuscular system that learns. Koffka points out, however, that Lashley's experiments show that the degree of localization of habits in certain areas of the brain differs with the habit. Brightness discrimination has a definite localization while the learning of which alleys to enter when going through a maze seems to be distributed over the entire cortex. Thus the maze can be solved without error when once learned even though later different movements than the original must be made owing to brain lesions which paralyze parts of the musculature.

Another point of view as to how transfer takes place was developed, particularly by Judd. Judd believes that in the *higher mental processes* transfer is the rule rather than the exception, and that systems of ideas can be carried over from one situation to another. Judd and others performed experiments to show that known generalizations are used to solve new particular problems and that subjects who gain insight into the principle by which a specific problem can be solved can then use it to solve another specific problem. Transfer will be aided if the learner is directed to generalize his experience in such a manner that a number of learning situations may be viewed as different manifestations of the same principle.

That reasoning or thinking can be improved in general is one of the major teachings of John Dewey and an objective of progressive educators. Dewey, however, is careful to point out that though a general method of attacking problems can be learned which will serve on all occasions, thinking cannot go on effectively when there is lack of knowledge of the data which are needed to solve the problem. What transfers, then, is past knowledge derived from past experience, and a method of gathering data and making and proving inferences, which is also derived

from past experiences. Neither Dewey nor Judd subscribes to the theory of formal discipline though both believe in transfer of learning.

Today's attack upon the problem of transfer is the attempt to determine how one can teach so that the maximum of transfer will take place. It has been found that transfer cannot be a vague objective, if it is to be an effective objective. The teacher must be quite clear as to what techniques, and generalizations, and attitudes she wants the student to carry over from one situation to another. The student, moreover, will not transfer generalizations that he knows by heart but does not understand. Rule-of-thumb procedures are equally ineffectual. Knowledge that is largely verbal and has had little connection with direct experience will not transfer to a situation where a practical application must be made. Transfer is aided if at the time when students are solving one particular problem, they are guided to name other problems in which the understandings being learned can also apply. Transfer of learning is itself a skill that can and needs to be practised. Students who are allowed to discover solutions for themselves or with a minimum of guidance are in each case transferring past experience to present. While there are individual differences in the degree to which the ability to transfer relevant past learnings can be acquired, this ability, like any other, can be improved.

While transfer in the field of knowledge and skill has been discussed as an ability, transfer in the field of attitudes and conduct has the characteristics of an attitude more than of an ability. An individual may show himself relatively inadequate in solving a particular problem or in memorizing a poem if he considers the task unimportant. His difficulty may remain, however, even when he attaches great importance to the task and has had past experiences which could be of help. In the display of neatness, or kindness, or honesty, or tolerance, ability plays the minor rôle and value the major one. The person "knows how" to behave a certain way but in this situation does not wish to do so. Because he was kind on many previous occasions does not necessarily mean that he will be kind now. The very pattern of his personality may be such that he is always kind

towards certain persons and always cruel towards others. In contrast, certain prejudices, likes and dislikes may snowball at very rapid speed. In the field of personality guidance the problem is as often the attempt to reduce likely transfer as it is to encourage transfer to take place.

Along with the theory of identical elements there arose the theory that conduct is specific and that there are few if any generalized traits. The direct teaching of learnings which "life itself would demand" was stressed. Education became more directly vocational and less formal and "cultural." It is now rather generally agreed that transfer takes place beyond the limits of mere content of subject matter, and that overspecialization of the curriculum along vocational and immediately practical lines may at times have taken place. No school subject, on the other hand, can reasonably be justified on its formal training value alone since this appears to be relatively small, or at least difficult to evaluate in an objective manner. The self-activity of the pupil, as issuing from both his general ability and the stimulation and direction of the teacher, is seen to be an important matter. Any completely satisfactory theory of transfer will probably be the outgrowth of the improvement of our present theories of learning, of which transfer is a phase. Experimental studies will contribute to this in proportion to the attention they give to the by-products of learning, over and above the performance itself which is practised and reproduced.

TRANSIENT CHILDREN. Transient children are children who travel from place to place across the country either in families or by themselves. In either case, they present both social and educational problems.

The causes of migration are numerous. Many families were forced onto the road during the depression in search of employment. Young people left homes to lessen the family relief burdens.

From 1933 to 1936 the Federal Government appropriated upward of 86 million dollars for the care of transients. The largest number of persons cared for in any one month was 300,460 in February, 1935. At the depth of the depression, it is estimated that at least 400,000 individual young persons were "on the road."

Under the Federal Transient Program (1933-35) some 300 camps for transients were established; these were later converted into work camps under the W. P. A. (*q.v.*).

Large numbers of migrant families in the West and Southwest follow the harvesting of crops in the hope of obtaining seasonal employment. This migration was accentuated by the drought in the "Dust Bowl" regions. Every year from one to two million men, women, and children move about the country seeking farm jobs. Between the middle of 1935 and the end of 1939, 350,000 persons of this type were counted entering California alone. In Texas and Oklahoma there are probably more than 50,000 roving cotton pickers.

The Farm Security Administration estimates that "there are probably between 250,000 and 400,000 of these farm families wandering around over the face of the earth."

Migrant families and their children present many social problems. Their annual income is low, and when their seasonal employment is cut off they are likely soon to be on relief. The Resettlement Administration in 1935 found average annual earnings of about \$250 per worker and about \$450-500 per family. Low earnings, unemployment, instability, insecurity, bad housing, hostility of the established residents, interrupted schooling, poor sanitation, spread of disease—all of these social conditions surrounding the migrant are especially bad for children.

The children of migrants put a burden upon the local school system which is often

TRANSPORTATION OF PUPILS

resented by resident taxpayers. Children are stigmatized at school as "pea pickers," "Okies," and "Arkies." Parents realize that their children are not receiving as good an education as they had themselves.

The problem of the allocation between private and public, state and federal agencies of the social and educational relief of these migrant families and their children is far from solution. The Interstate Conference on Transient and Settlement Laws (in March, 1936) emphasized the importance of both federal and state action. The Secretary of Labor has the responsibility of reporting to the Congress the results of surveys in this field with recommendations for legislation.

M.E.F.

TRANSPORTATION OF PUPILS.

The transportation of pupils to schools is a business of large proportions. In 1923-24 there were 837,361 pupils transported to schools in the United States; by 1937-38 there were 3,225,361 pupils being transported at an expenditure of \$61,032,340. This movement to transport pupils to school was begun first in Massachusetts; public funds for that purpose were legalized by that state in 1869.

The real development of pupil transportation has had to await the coming of better roads and the consolidation of schools. Originally, schools sprang into being at small centers of populations; as individual families moved into the surrounding territory and as land surveys were made, one-room schools were established, nine to the township or one for each plot of land two miles square, in many sections of the country. This placed a schoolhouse within easy walking distance of every child within the township.

But social needs gradually outgrew the one-room school; pressure for the consolidation of schools began to be felt. Then came the automobile and the demand for good roads that would provide for more effective use of this new means of transportation. This latter movement supplemented the former. Regardless of the need for consolidation, little progress could be made in that direction until means were provided for transporting pupils over greater distances. With the arrival of both the automobile and the hard roads, an ideal setting was arranged for the consolidation of schools and with it for the increased transportation of pupils.

Many problems face school authorities in making the transportation of pupils rapid, efficient, and safe. Reeder lists the following: "Shall the school district own the busses or contract for them? What standards shall the busses meet? How shall bus routes be planned? What qualifications shall bus drivers possess? How shall pupils who are transported be supervised? How may accidents be reduced or eliminated? What types of insurance, if any, shall be carried? How may costs be reduced without decreasing the quality of service? What records shall be kept?"

Not all of these questions can be answered definitely. Where the ownership of busses should reside is a most controversial problem. Many recent studies tend to show that school-owned vehicles make transportation cheaper; they also show that transportation in parents' automobiles is the most expensive. However, other criteria are perhaps more important than costs.

Standards for judging school busses probably will never be final, but the general criteria against which to check school bus construction are *safety, comfort, durability, and economy*. The planning of bus routes is most important; this actual transportation of pupils touches home life most intimately. If children are driven to school by long indirect routes or if a bus load of pupils has to wait for a single child, discomfort and sharp criticism result. The most important step in planning bus routes is the making of a transportation map of the district; this map locates and identifies all types of roads within the district and then spots the school children who must be transported.

The bus driver must transport pupils safely, supervise them en route, and care for his bus. It would seem, therefore, that a driver should be a man of moral character and good habits; he should be physically fit; and he should know transportation laws and practices for his district. In order to eliminate accidents, pupils as well as the driver should know the specific rules generally acceptable in governing their conduct while being transported; often, through ignorance, a youth so conducts himself as to endanger the safety of himself and others. Proper instructions to both driver and children can prevent many accidents. (See SAFETY EDUCATION.)

The following are the more common types

of transportation insurance: (1) bodily injury liability; (2) pupil accidents; (3) property damage liability; (4) fire and lightning; (5) theft, robbery, and pilferage; (6) tornado, cyclone, windstorm, hail, earthquake, explosion, and water damage; (7) full collision; and (8) deductible collision. (See **LIABILITY; NEGLIGENCE.**)

Unless the basic questions are answered satisfactorily by each school district that engages to transport any considerable number of pupils, school children may suffer extreme physical discomfort, acquire habits of bad conduct, and endanger health and life. The problem presented by the transportation of pupils demands the most careful consideration by school officials.

TRAVEL. Travel is an important means whereby teachers may enlarge their intellectual horizons. In some school systems it is the policy to base salary increases on travel; other school systems grant leaves of absence for travel on the theory that it is a worthy means of professional improvement.⁴

Many leading colleges and universities are granting college credit for tours conducted under the guidance of competent instructors. Price, who was on a scholarship from the Commission on Teacher Education of the American Council on Education in 1940, describes in glowing terms a 2000-mile summer session of touring and training for which he was awarded 9 quarter hours of college credit in social studies. Since his experience is typical of the way the sightseeing courses are conducted, it might be worth noting that the class spent a week on the campus before the tour began, during which time they listened to lectures on geography, economics, and other aspects of the trip, and read and selected some books to take along with them. After this, they spent the greater part of the summer session on a tour during which they actually saw social conditions and interviewed the people about whom they were

studying under tutorship of their instructor-guide. After the travel, a week was taken on the campus for summary, speculation, and talks by members of the group.³

The purpose of educationally planned tours, escorted by competent instructor-guides in various fields, is to supplement mere book learning with the rich first-hand experiences afforded by travel and to make these visits to shrines of human achievement of significant and enduring value. Before the second World War began, the American Institute of Educational Travel (Fifth Avenue, New York), offered each year a varied program of European tours under the direction of American college teachers, for which credits were granted in many colleges and universities of the country as the equivalent of corresponding work done in such fields as music, history, art, and literature.¹

Education through travel also has become popular in the elementary and secondary schools. Not many educators who read Fitzgerald's account of a summer tour with 26 youngsters on approximately \$14 for each child would care to stress the disadvantages of education by travel. Using an old school bus which the teachers had bought for the purpose, this tour covered hundreds of miles through Oklahoma, Tennessee, Georgia, North Carolina, Virginia, Pennsylvania, and New York, and Canada; and gave the rural children such educational experiences as visiting Niagara Falls, using Canadian money, and meeting senators, congressmen, and other prominent people in many places.² (See **TRIP, SCHOOL.**)

TRIGONOMETRY—See **MATHEMATICS, TEACHING OF.**

TRIP, SCHOOL. The school trip is a form of school activity in which pupils are taken out of the classroom for the purpose of providing them with sensory experience with people, things, and processes that cannot

be brought into the school. It is the most concrete of all audio-visual aids to teaching.

Classified with reference to the administrative arrangements required, school trips fall into four classes: (1) one-period field trips or visits to places near the school, which involve little or no collaboration with other teachers or with parents; (2) similar trips covering more than one period but not more than one day, which can be arranged by the teachers and principal of a school; (3) overnight or week-end trips involving parental cooperation; and (4) extended journeys of two weeks or more, for which special itineraries and all the arrangements for travel are necessary.

More frequently used in connection with science and social studies than with other subject matter, field trips are directed to acquiring first-hand experience and information about some topic or problem under study. Short field trips have the same general value as the longer school journey. Common objectives of field trips are museums for some specific kinds of exhibits; fields, woods, and farms for observing or collecting plants, animals, geological materials, etc.; manufacturing plants; public utilities, such as telephone exchanges and waterworks; and local government agencies.

Many values are claimed for this form of instruction: (1) The school trip supplies wide and varied experience organized in the pattern of the real world and constituting in itself the most liberal kind of education. (2) It supplies substance for the abstractions and generalizations of schoolwork, increasing interest, integrating subject matter fields, and bridging the gap between the school and the outside world. (3) It affords excellent opportunity for learning cooperation, courtesy, social adjustment, and business dealing in a natural situation. (4) It promotes understanding among different social, economic, national, and racial groups.

The school journey may be general in purpose, as the afternoon visit by a kindergarten class to a farm or the four-week vacation tour of the eastern states and Canada by a high school group; or it may be a part of instruction in some subject matter field. Among trips of the latter type are field trips by science classes to gather specimens or to observe animals, plants, or geological features

in their natural setting; trips to study local industrial or utility plants; visits to scenes of historic events or literary productions; tours of city, state or national government offices and buildings; and visits to art galleries, museums, observatories, theatres; etc. A trip to a milk pasteurizing plant may illustrate many of the principles of science and health that previously have been vague paragraphs in textbooks. Opportunities for such trips often exist within a block or two of the school building; they need not involve great expense or an undue proportion of school time. In fact, one of the most helpful trips that can be made in many schools is a carefully planned tour of the school building itself. The nurse may meet the group at the health office and explain the function of the school health service. The principal may welcome the group to his office and explain how the school records are kept and how a school is administered. The janitor comes into his own as an educator on such a trip, for the pupils are interested in learning how their building is heated, cleaned, and kept in good running order. Here is an opportunity for the pupil to become acquainted with his immediate environment, to learn valuable lessons of citizenship, to share in learning experiences, and to cooperate actively in carrying out a worth-while project.

More elaborate trips, usually called school journeys, may be taken with considerable benefit to all concerned. The children of some of New York City's schools have visited the coal mining regions of West Virginia, have lived with their southern neighbors, and have learned at firsthand the characteristics of their land, their work, and their common problems. The children of the coal mining towns have returned the visit and have had their horizons considerably broadened as a result. The children of the public schools of New York City have circled their city on municipal ferry boats and learned about their island metropolis. Many other schools have visited their state capitals and watched legislatures in action. Still others have visited the nation's capital to see, hear, and study their national government.

Whether the destination of the school trip is just around the corner or a thousand miles away there are certain basic principles which should be observed. The teacher should,

TRUANCY

whenever possible, take the trip beforehand, going over the ground carefully, studying the educational possibilities inherent in the situation, and planning the stops, the questions to be elicited, and their explanations. Careful planning includes: (1) adequate preparation of the class so that the students understand the reasons for the trip and their individual and group responsibilities for its success; (2) arrangements for transportation and, when necessary, for food and lodging; (3) preliminary discussion or correspondence with those in charge of the place to be visited so that they, too, understand what the class hopes to gain from the experience; (4) a planned procedure for student activity during the visit; and (5) provision for checking and integrating the results into the larger patterns of instruction by providing for appropriate follow-up activities. The best trip is the one that opens up new fields of interest, opportunities for creative endeavors, and the desire to investigate still further. When trips are carefully planned and conducted, the teacher can readily prevent the usual objections to school journeys and field trips, namely, waste of time and rowdyism.

The problem of the school's and the teacher's liability in cases of accident and injury to pupils in school journeys is a particularly pressing one. The legal responsibility of the school and the teacher varies in different localities (See **LIABILITY**; **NEGLIGENCE**), and it is advisable for the parents and the school authorities to be thoroughly conversant with the legal problems that arise in case of injury to the children. In any event, the teachers in charge bear the greatest responsibility for the safety of the children in their care and, in general, can be held liable in case of proved negligence. Some teachers find it advisable to seek insurance coverage for their financial protection.

More widely used in England, Germany, and other European countries than in America, the extended school journey is increasing in popularity here, and finds a place in schools of all grades—from kindergarten to university.

TRUANCY. The term "truancy" is not synonymous with "running away," but is used to describe prolonged absence from school without the knowledge of parents or guardians. In itself, truancy is not regarded as serious, but it often leads to delinquencies. (See **JUVENILE DELINQUENTS**.) The child's freedom from restraint, his feeling of guilt, and the fear of being apprehended, may cause him to seek undesirable hideouts, and to join asocial gangs.

The causes for truancy are numerous, and involve basic educational and social conditions, e.g., the child's dislike for school, unwholesome home situations, or excessive distances from school, as in rural areas. The child may have insufficient intelligence to understand and do the work expected of him in school, or he may be so intellectually superior that he is bored and will make no effort. He may dislike the teacher or feel that she has a grudge against him. He may receive low marks and fear that he will not pass. He may be ashamed or embarrassed by shabby or ill-fitting clothes. If he is tardy, he may be afraid to report at school or to return home. Hence, he may use truancy to escape from any of these unpleasant situations. Truancy may be a symptom of emotional instability, where the child uses it to express his rebellion against parental domination, to get even with or to punish someone, or to see the world. Some truancy, also, may be due to parents insisting that the child work, or to their indifference, ignorance, or antagonism toward the school.

The school's policy toward truants has changed from one of coercion to one of understanding the child, and the old-type truant officer has been replaced by a well-trained and sympathetic attendance officer, visiting teacher, or school nurse. Their services are often supplemented by counselors, clinical psychologists, and psychiatrists. There is no standard treatment for truancy, as each case must be considered in the light of its own

conditions. The school is taking measures to prevent truancy by instituting an elaborate system of child accounting with cumulative record cards designed to follow the child's progress from year to year, and to provide data about his personal adjustments. A school census is made each year, and teachers are required to keep accurate attendance records. Serious attention is being given to the adaptation of the school to the child's needs, abilities, and interests through the revision of pupil reports and marks, promotions, establishment of special classes, more challenging methods of instruction, and the selection of understanding and emotionally well-balanced teachers. Parent-Teacher Associations have been of considerable aid in supplying clothes, necessities, and scholarships to children from needy families. Progressive systems are giving more adequate health inspection, and better medical facilities; and are trying to acquaint the parents with the functions and nature of the modern school. Better transportation is being provided and many rural schools are being consolidated.

Some school systems have sought to punish truants by placing them in detention homes, where no educational facilities are available. Others have sent them to disciplinary classes or to truant schools where some educational work, primarily industrial, is given; thus the truants are kept off the street and away from bad company. The present trend, however, is to determine the child's motive through the case-study technique, and to prescribe and carry out corrective measures which will secure his adjustment to normal school conditions. Thus, where the home is too harsh, dominating, or uninteresting, the remedy may be found through the provision of some new adventure or legitimate thrill, such as summer camps, or properly supervised excursions. (See SOCIAL SERVICE ACTIVITIES IN SCHOOLS.)

The prevention and correction of truancy are sometimes relatively simple processes, but the treatment of habitual or prolonged truancy is usually a serious problem that is solved best by individual study of the child's difficulties. It is significant that the pupil personnel bureaus of large school systems find it advisable to educate their attendance officers to an understanding of the basic principles of case work. (See COMPULSORY AT-

TENDANCE; SOCIAL SERVICE ACTIVITIES IN SCHOOLS).

TURKEY, EDUCATION IN. *Organization.* The school system in Turkey is centralized. The Ministry of Education determines the curriculum, publishes textbooks, appoints departmental and provincial administrations, supervises the examination and certification of teachers and pupils, determines the locations of new and transfers of old schools, and in general initiates and controls all matters of policy. The Ministry comprises bureaus which are in charge of primary, secondary, higher, and vocational schools, and offices which supervise public libraries and museums.

Direct contact with primary and secondary schools is maintained through the 63 *vilâyet* (province) directorates, each of which is organized like the Ministry. Directors are assisted by inspectors who are specialists as to grades, subject matter, and types of schools. School principals carry local responsibility for adherence to curriculum, direction of teachers, and such matters as discipline. Faculty meetings are held not only for the distribution of orders, but also for democratic forums on school projects, problems of individual students, and discussion and decisions on recommendations to provincial directors and even to the Ministry.

Secondary, higher, and special schools are supported by the Central Government. Primary school expenses generally are included in *vilâyet* budgets and hence reflect local conditions, but the Ministry provides

TURKEY, EDUCATION IN

some elementary schools in the least prosperous and most backward places for the sake of raising national standards.

Movements. *Secularization* of education has not only been consistent with the new Republic's policy of separating "church and state" but has also been a means of escaping from the dungeon of the muslim parochial school system, which was ultraconservative in methods, subject matter, and conceptual framework. Achieved by legislation, this change was nevertheless well rooted in the decline of orthodoxy among the intellectually emancipated, and obviously necessary since organized Islâm was unable to finance the universal education which was recognized as a prime necessity to enable the new Republic to achieve stature as a modern nation.

The new alphabet, an adaptation of the Latin forms almost universal in the West and the Americas, adopted in 1928, is of great importance far less as an element of Europeanization than as an instrument of universal literacy. The Arabic letters, which had been in use, were so inappropriate to the language and so difficult to learn that children required three years to acquire a minimum of literacy and the whole educative process was accordingly retarded. This is one reason so much stress used to be placed on rote memorization. The alphabet in use is so consistent with the phonetics of the language that first-grade children achieve some facility in reading; spelling lessons are unnecessary; and the primary school period of five years is sufficient to accomplish about as much as requires six years in a typical American school.

Adult education received its greatest impetus from the adoption of the new alphabet. Within two years, 1928-1930, more than half a million men and women learned to read in evening classes, and in another five years the total exceeded 1,700,000—more than fifteen per cent of the population above primary school age. Instruction in civics and hygiene was combined with the literacy courses. While these special schools were not continued beyond 1935, most of the interested adults having taken the courses, adult education continues through lectures and study groups in the Folk Houses (*Halkevi*), agriculture institutes and bulletins, and non-military in-

struction to army recruits. The *Halkevis* are the chief centers of adult education and propaganda. The first 34 were opened in 1932 in as many provincial capitals and shire towns. Some of the buildings were rededicated *Türk Ocaks*, the centers of the Young Turk non-political, cultural activity 1908-1924. By 1941 there were 393 Folk Houses and 198 Folk "Rooms" (branches) in operation. Their nearest parallel in the United States is found in such institutions and buildings as Y.M.C.A.'s or churches or schools which are also centers of cultural activity for the entire neighborhood, with one main difference—the largest room in a *Halkevi* is not a gymnasium but an auditorium, usually with a stage suitable for dramatics, and sometimes an orchestra pit. Here are held concerts, lectures, plays, and dances. Other rooms provide for adult education classes, art and hobby exhibits and workshops, a library, and offices for the director and his staff. A standard, nine-fold program is outlined for all the Folk Houses. The nine *kols* (arms, i.e., departments) are (1) language, literature, and history; (2) fine arts; (3) dramatics; (4) sports (athletics); (5) social assistance; (6) adult classrooms and courses; (7) library and publications; (8) village welfare; and (9) museum and exhibits. Members are expected to concentrate their efforts, each in a single department; while they may act as associates in as many as two other branches, only in the one of their primary interest may they vote or become members of the executive committee.

Co-education is not yet a full-fledged social movement. Despite strong general emphasis on the emancipation of womanhood, there have been mixed secondary schools only where separate schools could not be financed. Whereas the leaders have been rightfully proud of successful co-educational schools, they have been unable to overcome the reluctance of conservative parents in the less accessible regions to let adolescent daughters attend classes with boys. A regime which has succeeded in achieving all the modernization goals for which it has conducted propaganda has not pressed this point while it was unable to provide enough schools for all. Co-education is becoming a "movement" only in that more and more girls are seeking and

TURKEY, EDUCATION IN

being permitted by their elders to enjoy it.

Government subsidy of students is a highly significant practice. Every year thousands of worthy youths receive not only tuition, but also all living expenses and pocket money for which they are indebted to the state only to the extent of working for a government agency, after graduation, at regular rates of pay two years for each year of subsidized instruction. The normal schools are operated entirely on this principle. Others include the special schools for health officers, agriculture instructors like "county agents," and the building trades school. There are also a number of boarding homes at which partial payment is in foodstuffs; other expenses are met by the Education Association, a private philanthropy.

Relations with American Education. There have been American schools in Turkey for over a century, but the attendance of Muslim Turks remained small until shortly before World War I. There are now two colleges (enrollment 1942-43, 1,500), three high schools, and a vocational junior high school conducted by Americans and supported by American philanthropy. The majority of teachers are Turks. Since 1931 not only primary instruction, but also the teaching of history, geography, civics, and sociology, as well as Turkish language and literature have been restricted to Turkish nationals. American institutions now surpass other foreign schools in the number of Turks enrolled. Since 1935 English has been the most popular foreign language in the public schools. Especially since İsmet İnönü became President, in 1938, cordiality of relations with American schools has been a policy. During recent years there have been from 75 to 150 Turks studying in graduate schools in the United States. This number is almost certain to be greater after World War II due to increases in the number of those speaking English, and in pro-American attitudes.

Statistics concerning education in Turkey require interpretation. The recent progress and the present welfare of the country are dependent more on the intellectual élite than the literacy of the masses. However, all available resources are being applied to achieve universal education. Whereas the crude literacy rates revealed in the 1927 census were 13% for males and 3.7% for females, the

census of 1935 found 23.3% of all males and 8.2% of all females to be literate. For the population aged ten and older, the percentages are 32.4 and 10.2 respectively.

The following figures show some of the progress between the first full academic year under the Republic and the most recent year on which reports are available:

<i>Schools</i>	1923-24	1937-38
Primary	4,894	6,700
Junior High	72	140
High	23	68
Normal	20	16
Vocational	44	47
Higher education	9	17

<i>Teachers</i>	1923-24		1937-38	
	Male	Female	Male	Female
Primary ...	9,021	1,217	10,483	5,292
Junior High	609 ^a	111 ^a	1,932	908
High	420 ^a	135 ^a	924	240
Normal	234 ^a	151 ^a	139	97

Higher education ...	349	0	739	98

<i>Pupils, students</i>	1923-24		1937-38	
	Male	Female	Male	Female
Primary ...	273,107	62,954	509,949	254,742
Junior High	7,976 ^a	2,076 ^a	53,883	20,224
High	1,622 ^a	612 ^a	16,107	4,893
Normal	1,745	783	1,209	1,598
Vocational .	2,757 ^a	619 ^a	5,088	2,486
Higher education ...	2,629	285	7,949	1,609

^a1924-25

The numbers of pupils in primary schools equal forty per cent of the boys, aged 7-12 inclusive, and twenty-two per cent of the girls. Since many rural primary schools cover only the first three grades, this means a large ratio of children is receiving enough education for literacy. M.W.W.

TUTORIAL INSTRUCTION. Tutorial instruction usually means instruction of a single student by a single teacher—a tutor. Such instruction is common in English universities but rare in American. Harvard, Vassar, and a few other colleges have used it successfully as a means of supplementing regular course instruction in preparation for final examinations. In effect, it is also used by institutions which have independent-study plans (*q.v.*) or regular individual conferences between teachers and students.

The term also sometimes connotes drill or coaching of an uncommendable kind, whereby tutoring schools or private tutors “cram” students for specific examinations. Such tutoring is often successful for its purpose and for pupils who cannot or will not study under ordinary school conditions, but it is widely considered to result in learning which is fleeting and poorly integrated. It is particularly uncommendable when it isolates the student from the associations of group meetings and extracurricular activities.

While this drill type of tutorial instruction was probably inherited from England, it is not the type now most prevalent in the leading universities there. The term there refers to unhurried, unforced weekly discussion of the significance and background of a subject, rather than to drill upon facts and skills. Such instruction may be highly effective because it stimulates truly individualized work under regular guidance and amid inspiring associations. (See PRECEPTORIAL SYSTEM.) M.G.F.

TWELVE-MONTH SCHOOL — See ALL-YEAR SCHOOLS.

TYPE STUDY. Since it is impossible under school conditions to study every detail in subjects, or to treat subjects in encyclopedic fashion, a movement was initiated about the middle of the nineteenth century by Karl Ritter in Germany to teach typical examples of major phases of subjects. The movement took hold first in geography, but spread to other fields. In this country, Charles and Frank McMurry effectively furthered the movement through their textbooks on method.

An illustration of type study in geography is the consideration of the rise and development of commercial and industrial cities by making a detailed study of one commercial and industrial city, such as New York, and then drawing a few comparisons with the development of other cities. Through the child's study of New York he should understand the rôles played by its excellent all-year harbor and large pier space, its situation at the mouth of a navigable river, its railroad and water connections with the West, and its strategic position for world shipping. From such a study of New York and the comparisons with the rise of other cities, a general background is built up which can be used to help the child understand the growth and development of many other commercial and manufacturing cities. Obviously no one can make intensive studies of all cities, but he can study a good model, or type, of one city and generalize as to the development of other cities falling under the same classification. The same general idea can be applied in botany, biology, history, and other subjects. In botany and biology, a type plant or animal can be studied in detail, then the knowledge of the plant or animal can be applied in a general way to all plants and animals coming under the classification used for the type study.

Today, the term *type study* is seldom used. Now, the unit, problem, or contract embodies the main thought of type study under such terms as transfer and generalization, but there is seldom intensive study of one case; the general concept is developed and the information is applied on a broad scale. In science, the topic may be how large cities get their water; here the topic is developed in a general way, and then this background is used in explaining how particular cities get their water. In geography, irrigation is studied in a general way, and applied to various regions of the world. Although the term as used by the McMurrays is replaced today by a different term, the essence of the type study is embodied to a considerable extent in modern pedagogy. (See GEOGRAPHY, TEACHING OF.)

TYPES OF PERSONALITY—See **TYPOLOGICAL JUDGMENT OF CHARACTER**.

TYPEWRITING. Typewriting in the secretarial curriculum was originally vocational in its objectives. The early instruction in typewriting was based almost exclusively on the theory of part learning; that is, the individuals learned letter location through repetitive practice of nonsense drills. These letters were later practiced in isolated words and then in context material. Speed on plain copy was the principal measure of success in learning. The learning theory was "Accuracy first, speed will take care of itself."

Significant researches in the learning of typewriting contributed materially to the improvement in instructional method. The publication in 1925 of *Learning to Type* by Book brought to the attention of teachers the importance of practice of consecutive sense material in the development of typewriting ability and pointed out the significance of particular kinds of error. Experiments in the teaching of typewriting by the whole method and studies of the behavior of expert typists have developed a trend in the teaching of typewriting by word patterns rather than by isolated lettermaking movements. Newer methods of teaching typewriting, therefore, tend to make it possible for the learner to type sense material more rapidly and in a shorter period of learning time than formerly.

The widespread use of the typewriter as a means of communication and the experiments by Wood and others in the use of the typewriter in elementary schools as an aid to learning have done much to increase the popularity of typewriting for personal use. This personal use of the typewriter has the effect of placing the typewriting course in the lower grades of the high school or even the elementary school so that pupils may have an opportunity to type their school work. Furthermore, instruction in composition on the typewriter has become an integral part of instruction in typing for perfection.

The demands of employment for higher transcription ability have made necessary actual instruction in typewriter transcription. The general use of typewriting for clerical work has also increased the enrollment in typewriting courses because of the need that clerical workers have for this skill. Courses in typewriting for vocational use are most

frequently given in the eleventh and twelfth grades. Specific changes in other areas of typewriter learning have resulted in the increased emphasis upon the typist's ability to produce typewritten work of a commercially acceptable quality at commercially acceptable rates. This has led to the development of an adequate number of mailable copies as a standard for typewriting classroom work rather than the older standard of the production of perfect copies. (See **BUSINESS EDUCATION**; **SECRETARIAL EDUCATION**.)

TYPOLGICAL JUDGMENT OF CHARACTER.

Typology is the simplification of differences among persons by classifying all persons into a few types and then deducing a large number of their characteristics from the type into which they have been classified. From as far back as ancient Greek times peoples were divided into the *melancholic*, the *choleric*, the *phlegmatic*, and the *sanguine*. Each of these four temperaments was supposed to correspond to a certain type of physiognomy.

Kretschmer, in more recent times, also divided people into several types according to physique and claimed that each of these physical types was correlated with a certain emotional type. Kretschmer believed that tall, slender, *aesthetic* physiques were introverted, romantic, idealistic, and had a tendency towards the dementia praecox type of insanity, while the stockier and heavier physiques, the *pyknic* type, were mainly extroverted and realistic, and, if they became insane, the tendency was towards manic-depression. Kretschmer also distinguished the *athletic* and *dysplastic* types, thus keeping to the ancient idea of four types.

Other typologists exclude the physical correlation but claim that the total pattern of man's character can be typed. Spranger's well-known classification of men into the

TYPOLOGICAL JUDGMENT OF CHARACTER

theoretic, the æsthetic, the social, the economic, the political, and the religious is of this kind.

The difficulty with typologists is that they claim to type the whole character, whereas in reality men in all their richness of personality variety can never be fitted into a few categories. For any one characteristic, however, thinking, in terms of types rather than in terms of infinite variations may be helpful, even though actual measurement and observation show that individual differences form more or less of a continuous distribution, and that this is as true of emotional and char-

acter traits as it is of skills and abilities.

Jung's division of mankind into *extroverts* and *introverts* is thus still popular even though psychologists no longer believe that the trait is a dichotomous one. (See INTROVERSION.) Furthermore, introversion-extroversion is no longer considered an all-embracing trait which greatly influences every phase of character and personality in an expected direction. Popularly, character is still described in terms of types, but scientifically, character description must be made in terms of a large number of variables to bring out the uniqueness of individuality. B.B.F.

U

UNDER-PRIVILEGED CHILDREN.

Under-privileged children may be defined as (a) those who suffer from special disadvantages, (b) those who are not born under conditions of opportunity equal to the conditions under which other children are born, (c) those who live in families or under conditions below the normal standard of living.

These under-privileged children may be further classified as follows:

1. Children in rural areas.
2. Children in families of low incomes.
3. Negro children and children of other minority groups.
4. Children in congested city neighborhoods.
5. Out-of-school, and unemployed youth.
6. Children with mental, emotional, or physical handicaps.

The number of children living in families on relief was variously estimated from 11,000,000 in 1934 to 7,000,000 in 1940.

Children from families who belong to some minority racial or national grouping live under severe handicaps. These include more than 4,000,000 Negro children and about 8,000,000 children of foreign born or mixed parentage.

Nearly a million children of elementary age are not in school.

It is clear from this enumeration of the various categories of under-privileged children that these children constitute no homogeneous group, with all children having the same problems and suffering from the same kind of handicap. The child in a rural area may be under-privileged so far as his opportunity to profit from a richly varied educational program is concerned, but his emotional, physical, and social problems are totally different from those of the Negro child and even from those of the white child who lives in a poor socio-economic environment.

The influence which his being under-privileged has on the child depends on the nature

of the deprivation and on its psychological and social implications. Thus, a child from an impoverished family living in a community where all his friends are poor may suffer from some of the physical results of poverty with its accompaniment of poor food, inadequate medical care, bad housing, etc., but he may not suffer the psychological and social results of poverty as much as does the child who lives in the slum district of a suburban community.

The American emphasis on political and social democracy and on equality of educational opportunity has led to numerous attempts at improving the lot of the under-privileged child. In recent years, additional attention to the needs of these children, especially to those coming from poor socio-economic groups, has come from a growing realization of the social problems created by the neglect of these children. Thus, studies of juvenile delinquency have indicated that some neighborhoods in large cities have disproportionately large delinquency rates.

Though considerable improvement has been effected in the treatment of each of these groups of under-privileged children, they still present a serious social and educational problem for which no ready solution is available. The situation is further complicated by the fact that the solution involves more than educational procedures. Because the problems arise from so many sources, the solution must take many forms. The improvement of facilities for the education of handicapped children, for Negro education, and for rural education (*qq.v.*) all have their contribution as have also the extension of unemployment insurance and other means of improving social and economic security, the extension of recreational facilities (See ALL DAY NEIGHBORHOOD SCHOOL; RECREATION), the improvement of housing conditions, and similar improvements in living conditions. (See also M.E.F.)

UNGRADED ROOM

UNGRADED ROOM. The term ungraded room has various meanings: (1) The one-room rural school is referred to as an ungraded school or room regardless of whether it attempts to grade its pupils or whether the pupils are taught, as in the days of the "little red school house," without any standardization of offerings. (2) The classrooms that house children of low academic ability are referred to as ungraded. (3) Classrooms that house children who have created disturbances in regular classrooms and who, therefore, have been segregated for instructional purposes are known as ungraded. (4) Able children who are candidates for rapid promotion or who, due to illness or other causes, are retarded in given subjects are also taught in so-called ungraded rooms.

The ungraded school room of the rural area has had several stages of development. There was the day of the truly ungraded room or school in which a sequence of studies, taking children from the first grade through the eighth, was unknown. Children enrolled, attended a few weeks or a few months, and left. They brought whatever books the family happened to own. They studied these books without reference to books being studied by other children. This represents, perhaps, the truly ungraded room or school.

Then, influenced by urban school practices, attempts were made to grade the program of studies so that definite school work was required in the first, second, and on through the eighth year of the elementary school; courses of study were devised, and uniform textbooks came into being. The children of this recent type of one-room rural school are graded, but the school is still referred to as ungraded. Such a school faces the problem of many recitations of short duration. Modern rural education seeks to meet the needs of pupils in these ungraded rooms by a happy combination of individual and group instruction whereby larger groups of pupils may work together upon many projects and whereby the individual may receive the particular assistance needed to enable him to participate in the group. (See *RURAL EDUCATION*.)

The ungraded room for pupils of low academic ability originally enrolled pupils ranging in age from 8 or less to 16 or more; they were segregated from other children; they were given an unusual amount of hand-

work; and they were given a program which was designed to make them happy. Today, these rooms are commonly grouped two or more to a center. The children are a recognized part of a regular elementary or junior high school; their school program is aimed at making them better able to do those things they are likely to do anyway in the particular community of which they are a part; certain abilities that they have are being recognized and used in the school's activities. Some educators insist that even this amount of segregation should not exist. Other educators assert that this recent procedure is not segregation any more than separation of a first grade group from a second grade group is segregation; they insist that a school program has been provided that best meets the needs of these children just as the work provided for the second grade meets their needs more adequately than it would meet the needs of children just entering school for the first time.

The ungraded room for disciplinary problems is provided in some school systems, but has not had wide acceptance. It has tended in the past to be a room for punishment rather than for diagnosis and help. As a result, children sent to such rooms have been more or less stigmatized. The few school systems that have established these rooms have tended to organize them solely for boys. The rooms are the by-product of urban education and are usually found only in large elementary and junior high schools; they are often located in basement rooms and supervised by a man known more for his physical ability than for his human understanding of boys who have "cracked" under typical school discipline. Theoretically, this type of ungraded room aims to help these boys so that they will be able to return shortly to their regular school grades.

The ungraded room is rarely used for children of good academic ability. When used, its aim is to give these children additional help so that they may "skip" a grade or "make up" work that they missed because of absence from school for sickness or other causes. Sometimes an ungraded room will house two or more of these various types of children. (See *ONE-ROOM SCHOOL*.) A.O.H.

UNIFIED STUDIES. *Unified studies* refer to the alternate teaching of blocks of the related subject matter of two subjects from separate areas, in which the carrying continuity is usually determined by one of the subjects. For example, the chronological sequence of history furnishes the organizing base of a study of history and literature. Such studies are usually taught by two teachers, one representing each subject but working simultaneously with the pupils over a double period. Thus the time pupils spend on each subject is no greater than if the subjects were taught separately. Teacher load may or may not be increased.

The unified studies approach to curriculum revision originated in secondary schools in the early 1920's as an improvement on the schemes of correlation (*q.v.*) then in practice. The best planned correlations were unsatisfactory in practice because of the separation of classes and the failure of each teacher to know how the relationships were developed by the other. Bringing the two teachers together in one class with the same pupils for a longer time appeared to be a solution of this difficulty. Thus the early attempts to make planned correlations more effective led to the beginning of the unified studies approach.

Teachers of such unified courses found the arrangement unsatisfactory, however, because of the dominating control of one of the unifying subjects. They began fusing subject matter within the two subjects and drawing upon other subject matter within or without the two general fields. Soon other subjects were added as a regular part of the unification. Illustrations of this are Social Studies, English and Art or Science, English and Mathematics or Home Economics, English and Art. Since 1935, experimental secondary schools have increased to three the number of cooperating teachers, the number of subjects represented, and the number of periods per day. The result is called a *core curriculum* (*q.v.*) of the subject type. Thus

unified studies are now frequently called a core, broad-fields, or integrated curriculum.

There are two main types of unified studies. First and more prevalent is the type of unified study which adheres closely to the original subjects and the subject viewpoint. The organizing principles are within the subject matter and controlled by the teachers, even though much new material may be added. Culture-epoch courses, organized on a chronological basis and the adult needs approach to the essential material, are illustrations. The second type of course derives much of its content from a study of the immediate problems of learning of the enrolled students who cooperate with the teachers in the management of the course. Such a unified studies course approaches the qualitative learning of the experience curriculum and is advocated by many persons as the best practical departure from the subject organization. Others believe that unified studies reorganize too small a part of the total school program to have any permanent effect in improving the curriculum. (See CURRICULUM.) L.T.H.

UNION OF SOCIALIST SOVIET REPUBLICS. EDUCATION IN. In the school year 1938-39, just before World War II, the total population of the U.S.S.R. was 170,467,186 and the enrollment in the regular schools—excluding kindergartens and playgrounds, and special courses—was 34,173,200. Of these, 21,333,500 were in primary schools, 12,236,800 in secondary schools, and 602,900 in higher institutions, which are respectively 1.9, 10.7, and 3.6 times the per capita enrollment in 1913-14, under the Czarist regime, just before World War I.

The U.S.S.R. primary school admits children at the age of eight; it is not exactly a beginners' school, for the ability to read is a prerequisite for admission. It is being preceded more and more by systematic pre-school training in kindergartens for three to seven-year-olds (approximate 1938 registration, 4,000,000; all children to receive such training by 1942, according to plan). Furthermore, the primary school sometimes in-

UNION OF SOCIALIST SOVIET REPUBLICS

cludes a preparatory zero-class for seven-year olds. It has four grades and brings the children up to approximately the seventh or eighth grade of the American elementary school.

The Soviet secondary schools give a *general six-year course*, which is divided into two equal halves. The first three years are known as the *incomplete secondary school*, corresponding in program to our junior high schools, and the last three years, the *complete secondary school*, being a year or so in advance of our senior high schools. Teachers in *incomplete secondary schools* must have two years of higher pedagogical training, and those in *complete secondary schools*, four years. The *technicums* admit students from the *incomplete secondary schools* and offer two years of general education and two years of special training, graduating primary school and kindergarten teachers, nurses, medical and laboratory assistants, and a variety of "lower rank" technicians in agriculture, industry, distribution, communication, and transportation. The *workers' faculties*, taking students of eighteen or older, are essentially short-cut preparatory schools for capable adult workers lacking a secondary education and desiring to enter an institution of higher learning, while the *factory apprentice schools* are designed for adolescents, fifteen to eighteen years of age, needing a special and general secondary school training for their work. Attendance at the *workers' faculties* and the *factory apprentice schools* is diminishing, as incomplete and even complete secondary education is gradually becoming compulsory.

Higher institutions in the U.S.S.R. admit students from eighteen to thirty-five or forty years of age who have a *complete* secondary education. They afford from two to six years of study in some professional or general institute, academy, or faculty. Most of them offer also three years of individual post-graduate work, leading first to the "candidates" degree (comparable to the American Master's degree) and then to the Doctor's degree. In 1938, there were 708 institutions of higher learning. There were 91 in 1914.

Finally, one may include the enrollment of 13,533,500 students in special courses, mostly "liquidation of illiteracy", and "political education" class for adults; and some statistics on the press are also relevant. In 1938 Soviet

libraries possessed 146,602,900 volumes, and in the same year 692,700,000 copies of new books and pamphlets were published. The average daily newspaper circulation was 37,520,000. Nearly one-third of the books in the U.S.S.R. and one-fourth of its newspapers (according to titles and not total circulation) are published in 94 languages other than Russian.

Soviet education for many years was very "progressive" in methodology. It used, from kindergarten to university, what was known as a "complex-theme-laboratory-brigade" method, essentially a plan of mostly spontaneous projects and often fluid groupings. There were no textbooks, no single assignments, no individual responsibility, frequently no fixed class and teacher, and of course no marks and failures. Soviet educational research was busy collecting empirical data on students' action and discussing optimum composition and interpenetration of groups, and the best socialist "complex themes" at different levels of development and degrees of specialization. However, the results of these methods proved so unsatisfactory—sometimes described as disastrous—that in 1932 the entire practice was utterly condemned and summarily abolished. Since then Soviet educational methods have been much more conservative. The "planned lesson" has become the basic unit of instruction; classes and teachers are invariably permanent; courses are mostly prescribed; and assignments and textbooks are very definite and specific. In 1936 alone 126,000,000 textbooks were published for primary and secondary education. There is a four-category system of marking, as well as such familiar practices as final examinations, failures, competitive entrance examinations, exemptions for good students, and rapid promotions. In general, contemporary Soviet methods of instruction differ but little from those of the United States. To be sure, a greater emphasis on team work and so-called socialist competition does exist, but the instruction itself is focused upon the individual whose knowledge of facts, mastery of material, and well-rounded comprehension of subject-matter are constantly emphasized, tested, and rewarded—rewards and punishments being particularly easy and effective, as so many students receive stipends from the government.

UNION OF SOCIALIST SOVIET REPUBLICS

Stipends and scholarships in the U.S.S.R. deserve special mention. Stipends increased yearly in number and amount until 1939, when ninety-one per cent of all students in *technicums* and higher institutions were being benefitted by amounts ranging from 100 to 400 rubles (a ruble is officially about 20 cents) per month. The 400 rubles were received by post-graduate students whose allowance were thus about ten per cent higher than the average wages of a Soviet worker. However, in 1940 it was decreed that only students excelling in their studies, variously estimated from one-third to one-half of the entire students body, would be given stipends. Furthermore, tuition fees of 300-500 rubles a year for institutions of higher learning and of 150-200 a year for the last three grades of secondary schools were introduced. Scholarships were unaffected by the decree, and they are quite generous and plentiful in the U.S.S.R. There are 1000 scholarships of 1000 rubles a month and 2000 of 500 rubles a month for regular students of higher institutions, besides 100 of 1000 rubles a month for post-graduate students preparing for the "candidate's" degree and 50 of 1500 rubles a month for students preparing for the Doctor's degree. A thousand rubles a month is more than a university instructor earns and 1500 rubles a month equals the salary of a full professor. One may also add that the Soviet government awards each year 33 first prizes of 100,000 rubles each, 25 second prizes of 50,000, and 30 third prizes of 25,000 rubles for various research publications, discoveries, inventions, and works of art and literature. In all, studying in the U.S.S.R. is certainly not without individual competition and incentive.

Another phase of education in the U.S.S.R. which has recently undergone drastic changes is the use of intelligence tests. In the first years of the Soviet government these tests were enthusiastically accepted and widely acclaimed. They were hailed as powerful objective weapons in the socialist reeducation of the masses. The Binet scale was not even re-standardized, but merely translated into Russian—and other languages of the Soviet peoples—with only such understandable modifications as the change of "There are three differences between a president and a king. What are they?" to "There are three differ-

ences between a proletarian and a bourgeois republic. What are they?" A larger number of "special" classes of "difficult", "border-line", and "dull normal" pupils was set up on the basis of test questions, of which many were foreign to Soviet children. It was obvious that such an uncritical practice would not continue long and would eventually clash with Soviet social theory. A dramatic instance was provided when a wide testing program in Middle Asia disclosed the average IQ's of the native children to be in the 80's and even the 70's. This immediately provoked the sharp comment that educational psychologists uphold "racistic" doctrines. Then, it was found that the subnormal classes consisted mostly of children of poorer peasants and factory workers, which again aroused the criticism that intelligence testing tends to perpetuate economic class distinctions, sets up IQ castes, and obstructs the ideals of a classless society. The belated suggestion that the tests be properly standardized on Soviet populations and that IQ differences need not result in different teaching units was little heeded. In 1936 the Central Committee of the Communist Party merely abolished all intelligence testing of school children and ordered all school psychologists to retrain themselves for other occupations. It is interesting to note that at present intelligence testing is condemned even if one maintains that differences in scores are products of the environment. It is simply argued that psychometrics in general is a static, fatalistic doctrine, detached from the dynamics of mental development and engaged in piling up artificial, "casuistical" tasks which do not reflect reality and which only minimize the true and creative rôle of the teacher in school and outside school.

The distinctive features of Soviet education stem directly from its very close and conscious gearing to the economic needs and political demands of the country and the philosophical views of Communism. To a large extent, only those subjects are taught and those attitudes fostered which meet or emphasize these objectives. This results, on the one hand, in an education that is rather vocational or applied. (Soviet educators refer to it as *polytechnical*.) Studying and working are so concretely connected, and programs and interests are so much molded by

UNION OF SOUTH AFRICA, EDUCATION IN

future jobs—which, by the way, are always obtainable or even pre-determined—that some traditional material is kept out or under-rated, and some is made to serve direct practical needs. On the other hand, these very objectives give the same education a general or even academic tinge, inasmuch as each school must inculcate a certain general doctrine and must relate itself to social ideals. Soviet children often exhibit uncanny philosophical and social sophistication, and Soviet specialists probably possess more “outside” knowledge than any comparable group in any country. In all, Soviet education appears to have produced, at least in the younger generation, a way of doing and thinking and an integration of skill, knowledge, attitudes, values, and morale which have shown, as events prove, a remarkable cohesive consistency and a redoubtable resistance to disruption. Basically, the difference between education in the U.S.S.R. and in the U.S.A. is the difference between a land in which there is only one philosophy and one in which many and even conflicting philosophies are not only possible but do exist.

UNION OF SOUTH AFRICA, EDUCATION IN. The Union of South Africa is a dominion of the British Commonwealth of Nations, comprising the provinces of Natal, Transvaal, The Cape of Good Hope, and the Orange Free State. In area the Union is approximately 472,550 square miles, with a total population of more than nine and a half million, of whom 20.9 per cent are “European” (“persons of pure European descent”), and the rest (79.1 per cent) “Non-European” (“Natives—pure-blooded aborigines of the *Bantu* race,” 68.8 per cent; Asiatic—natives of Asia and their descendants, mainly Indians,” 2.3 per cent; and “Coloured

—Cape Coloured, Cape Malays, Bushmen, Hottentots, and all other persons of mixed race,” 8 per cent.)

“European” and “Non-European” children do not attend the same schools. There is complete segregation. European education is mainly public or state education, while non-European education is mainly state-aided education, partly supported and controlled by mission enterprise. It is necessary, therefore, to consider the education for Europeans and the education for non-Europeans separately.

European Education. The Act of Union (1910) by which the four provinces united to form the Union of South Africa, introduced a unique separation of control over and responsibility for education between the Union government and the provincial authorities. Only “higher education” (i.e. the universities) was made the responsibility of the Union government, while “education other than higher” was relegated to the provinces. Since 1910, however, the Union government has from time to time stepped in and taken over certain educational functions which it considered should, in the interests of the nation, come under national control. Moreover, the provinces were financially too weak to finance certain types of education which otherwise would have been their responsibility. Thus, such types of educational activities as industrial education, child welfare, agricultural, vocational, technical, and special education were by successive acts of legislation declared by the Minister to fall under “higher education,” and so under the Union government. Though originally the term applied solely to university education, it now includes educational services from the kindergarten to the highest post-graduate classes of the universities.

Approximately 94 per cent of the European children attend public schools. Traditionally, the state or public school is the school most children attend whatever their rank or economic position. The private schools, attended by a very small minority of the children, are very little different from the public schools in organization and curriculum, mainly because their pupils generally take the same state schools examinations the other students take.

Primary and Secondary Education:

In each province the executive and legislative authority over primary and secondary education (including the training schools for teachers) is vested in the Provincial Council and its Administrative and Executive Committee. A superintendent or Director of Education as head of the Department of Education, is the chief responsible officer. Under the director is a staff of inspectors who control the inner working of the schools.

An interesting feature of educational control in the Cape, Transvaal, and the Orange Free State Provinces is the Local School Committee elected for each school by the parents, whose chief function (in conjunction with the District School Board) is the selection of teachers subject to the approval of the Department where the appointments are made. There is also a District School Board which deals with general administrative matters pertaining to all the schools in its district. The fourth province, Natal, has no local educational authorities; all matters are controlled by the Department of Education at the provincial capital.

While there is some variation among the provinces, the following features of primary and secondary education are generally common to all:

1. Compulsory attendance from seven to fifteen or sixteen years inclusive. (Exceptions are made for students apprenticed in a recognized trade, in which case students may leave earlier). Education is generally free up to the last compulsory attendance age except in Natal where only primary education is free, and in the case of certain special schools.

2. Students on the various levels of secondary education are subject to state examinations of two general types—the Junior Certificate Examination given at the end of the eighth standard and the Senior Certificate (or School Leaving, or Matriculation Examination) at the end of the final tenth standard. These examinations are under the control of the provincial education departments and are administered under the direction of commissions consisting generally of representatives of school inspectors, normal schools, secondary schools, universities, and the Union Joint Matriculation Board. Students cannot continue in an advanced course of education

beyond the secondary school level without having passed a senior examination.

3. No sectarian or doctrinal religious education is allowed in the public schools. However, courses in Bible history—subject to a conscience clause—are generally provided, and the practice of opening the school day with a prayer and a reading from the Bible is followed in all public schools.

4. Teachers are educated in training institutions maintained by the provinces, and are licensed after having pursued satisfactory courses of training and passed the official examinations for their respective grades. The types of teacher-training courses and certificates vary; the practice followed in the Orange Free State may be cited as typical:

“The minimum requirement for appointment as a teacher in public schools is the possession of the Lower Primary Teacher’s Certificate . . . or its equivalent . . . Professional Teacher Certificates are of several classes—Lower Primary, Higher Primary, Advanced Primary, Professional Technical, and Secondary Grades I and II. The minimum requirements for the admission of candidates to these examinations are as follows:—Lower Primary: Matriculation or equivalent certificate and two year’s training at the Normal College; Higher Primary: First year B.A. course in certain specified subjects or one year at the Normal College; Infant Teacher’s Certificate: Lower Primary or Higher Primary Teacher’s Certificate and one year’s training in Infant School work at the Normal College; Advanced Primary: Higher Primary Teacher’s Certificate or equivalent. second year degree course and five years’ experience . . .

The Secondary Teacher’s Certificate is issued without further examination as follows:—

Grade I. To teachers in possession of a) the B.A. degree or equivalent academic qualifications plus the M.Ed. of the University of South Africa or equivalent professional qualifications, or b) the M.A. degree of a recognized university, or equivalent academic qualifications plus any recognized professional teacher’s certificate . . .

Grade II. To teachers in possession of the B.A. degree of a recognized university

UNION OF SOUTH AFRICA, EDUCATION IN

or equivalent academic qualifications, plus any recognized professional teacher's certificate . . .

An example of requirements given in more detail is the following:

"Candidates for admission to the Higher Primary Teacher's Examination must produce evidence to the satisfaction of the Board—

- a) that they have followed a first-year course at a recognized university or university college and presented themselves for examination in the following four subjects, and that they have passed the prescribed university or college tests in at least three of these subjects at one and the same examination:
 - i. first official language; ii. second official language; iii. Biological Science . . . iv. History or Geography or Mathematics or Physics or Chemistry or Geology;
- b) that they have attended a course of at least two years' duration at an approved institution.

The use in South Africa among the Europeans of two official languages, English and *Afrikaans*, brings with it educational problems unique to an officially bilingual country. About two-thirds of the Europeans speak both languages. Classified according to home language ("mother tongue") there is a wide difference between rural and urban areas. (Urban areas, 53 per cent English, 41 per cent *Afrikaans*; rural areas, 84 per cent *Afrikaans*, 14 per cent English). Most of the schools use one of the two languages as the medium of instruction and teach the second in terms of the first. According to statistics of June 1939, about 35 per cent of the students in primary and secondary schools were taught with English as the medium of instruction, 60 per cent with *Afrikaans* as the medium of instruction, and about five per cent with both English and *Afrikaans*.

University Education: The Union of South Africa has five universities.—South Africa (an examining body), Cape Town, Stellenbosch, Witwatersrand, and Pretoria, with an average yearly total enrollment of 10,505 students (1939), 261 full-time professors, 431 full-time lecturers and assistants, and 392 part-time professors, lecturers, and assistants. The cost of college and university education

is borne partly by student fees (39.15 per cent), partly by government grant (42.79 per cent), and partly by other institutional income (18.04 per cent).

The universities and university colleges offer a wide variety of courses of study leading to many types of degrees, from the academic arts and sciences to degrees and diplomas in medicine, agriculture, industrial chemistry, commerce, and social work. In addition, most of the universities and university colleges are actively engaged in extension work in the form of public lectures, social welfare activities, vacation courses, and the rendering of advice and assistance to other public agencies. For example, the Department of Educational Psychology of the University of Stellenbosch undertakes the observation and treatment of psychological and educational defects of school children, and assists the schools in the classification of children; the University of Witwatersrand is associated with the Transvaal Worker's Educational Association in giving extension lectures and tutorial classes.

Matriculation examinations are controlled and conducted by a Joint Matriculation Board consisting of representatives of the five universities, the Provincial, Union, South West African, and Southern Rhodesian Education Departments, and of teachers of public and private secondary schools. Professional examinations in law, surveying, civil service, etc., are administered by a Joint Committee for Professional Examinations composed of ten representatives from the universities and five appointed by the Governor-General.

Technical, Vocational, and Special Education:

The Union Department of Education administers technical colleges, industrial schools, trades and housecraft schools, and schools for the deaf and blind under the extension of powers previously mentioned. In addition, the education of the mentally defective children is administered by the Commissioner of Mental Hygiene under the Department of the Interior.

There are eight technical colleges with a total of 2,385 full-time and 12,492 part-time students (1939) of whom the majority pursue commercial courses. There are also a total of 37 (generally post-primary) state voca-

tional schools, of which sixteen are Trades and Commercial Schools, twelve Housecraft Schools, and nine so-called Industrial Schools to which children are committed for reasons of destitution, delinquency, or neglect.

Non-European Education. Non-European education is mainly state-aided education partly supported and controlled by mission enterprise. A distinction is made in the provisions for Natives (pure-blooded *Bantus*), and Coloured and Asiatic students (Indians, Cape Coloured, Bushmen, Hottentots, and mixed races). Native education is under the control of the provincial education departments assisted by the Chief Inspector of Native Education, and an advisory board representative of the missions controlling the schools. There is a growing movement to place native education under the direct control and administration of the government. A movement toward secularization is also evident among the natives themselves, who would like to obtain a larger direct share in its management. However, the overwhelming majority of Native schools throughout the Union are aided mission schools under the local control of a missionary manager. In the Cape many managers of schools are Native ministers; in the other provinces it is ordinarily required that managers shall be Europeans nominated by the missions concerned. About 6.5 per cent of the total Native population attend school (as against 19.7 per cent among Europeans), of this number only 2.24 per cent are enrolled in post-primary classes (as against 19.4 per cent among Europeans). The character of Native education is distinctly different from that prevailing in European schools. For instance, the following are some of the distinguishing features of Native education in the Province of Natal: a) an emphasis upon the study of the *Zulu* language, b) a bias towards the study and practice of agriculture, promoted by means of nature study and the cultivation of school gardens, c) an attack on superstition by means of practical hygiene, and later on by the study of physiology, and d) the improvement of manual skill by means of indigenous arts and crafts.

While native students are not barred from following courses at the European university institutions, very few actually do study

there. The only native institution doing work of a university standard is the South African Native College at Fort Hare, which enrolled 162 students in 1939. The principal courses of specialization are theology, education, and medical aid. The course for the training of native medical aids is a recent addition. The course includes scientific training and practical work in a large public health or hospital area. Candidates are carefully selected and will be employed upon graduation as medical aids in native areas.

Schools for Asiatic and Coloured students are administered by the provincial education authorities. Only in Natal, where the number of Asiatics is comparatively large (there are few Asiatics in the other provinces) is there a separate administration for Asiatic and for Coloured education. About 15.8 per cent of the Indian and Coloured population are enrolled in schools, but only 2.59 per cent of the school population are enrolled in post-primary classes. Unlike Native education, the curriculum in Indian and Coloured schools generally follows that of European schools. L.P.T.

Union of South Africa, *Official Year Book, 1941* (Union Office of Census and Statistics, Pretoria, 1941).

UNION SCHOOL DISTRICT. The legal designation of school districts as union school districts is used in New York State and to a lesser extent in some others. The specific type of district referred to is the union free school district which was created by act of the legislature in 1853 as a step in the consolidation of small school districts and for the purpose of levying taxes for the support of a high school. Some of the union free school districts in New York are city and village districts, and some are rural districts. In 1936-37 there were ninety-seven such districts in villages of 4,500 population and over, and 474 classed as rural districts, open country, and villages under 4,500 population.²

In a more general sense, union school districts are districts formed by the union of two or more districts for some specific purpose; supervision, or the establishment of a high school. Examples of such districts are the

supervisory union in New York, the New England States, the supervisory districts in Nevada, and superimposed high school districts in California, Illinois and other states.

The supervisory union in New York and in the New England states is an intermediate unit between the local district and the state, established primarily for the purpose of school supervision. In New York the supervisory union is headed by a board of directors, two of whom are elected from each of the districts composing the union. The board meets once every five years for the purpose of electing a district superintendent. The district superintendent's duties are chiefly advisory.¹ (See SUPERINTENDENT OF SCHOOLS.)

In the six New England States supervisory unions are formed by two or more towns under a school committee composed of the several school committees or a joint committee composed of one member from each. The duties and responsibilities of the joint committee vary, but usually they employ the superintendents and adopt policies concerning the distribution of his time and determine the proportion of his salary to be paid by each of the towns in the union.

In some states unions are under the direct supervision of the state. In New Hampshire appointment of superintendents is made by the state board of education on recommendation of the local committees, and in Connecticut sixteen unions are administered by state supervisory agents.¹ In addition to the county as an intermediate unit, there are five supervisory districts in Nevada, each composed of from one to five counties. Each supervisory district or union has a deputy superintendent appointed by the state department of education.

Another type of union school district is the superimposed high school district common in California and Illinois. This type of district was organized to offer high school facilities in areas where many of the small districts could not maintain schools beyond the eighth grade. Such districts are usually controlled by a separate board of education distinct from those governing the elementary school in the area composing the high school district.

In districts where a separate union school is maintained it is usually a centralized ele-

mentary and high school or a separate high school. All of the various types of union districts are examples of an attempt to overcome the disadvantages of the small school district. (See also CENTRALIZED SCHOOL and CONSOLIDATION OF SCHOOLS.) W.C.R.

UNIT PLANNING AND TEACHING.

A unit may be either *an experience* or *a body of subject matter*, according to the philosophy accepted for curriculum development. According to Morrison, a unit of work is "a comprehensive and significant aspect of the environment, or of an organized science, capable of being understood rather than capable of merely being remembered." Bruner says that "a unit is so organized that everything that is included in the way of content, the organization itself, and the method of presenting it to the class is for the purpose of making it possible for the child to grasp the big understanding or theme that is back of it." A unit of work, as it is conceived by the staff at the Lincoln School (Teachers College, Columbia University), is "a series of worthwhile experiences bound together around some central theme of child interest. Some incident serves as a starting point to arouse such an interest; activities of a compelling nature further stimulate this interest; information from almost every branch of knowledge is drawn upon to answer the questions which arise; individual expression of this interest is encouraged through various media." Jones, Grizzell, and Grinstead's *Units of Adaptation*, which are defined as "a group or

chain of planned, coordinated activities undertaken by the learner to obtain control over a type of life situation" are contrasted with "Units of Subject Matter" and "Center of Interest Units." Others would designate such units as "integrated," a term causing some confusion because it utilizes a word that has definite psychological connotations. Still others use the term "experience unit" to describe the concept involved. In this discussion we shall use the term "integrative experience" unit.

Many curriculum workers are coming to look upon a unit of work as a complete experience based upon a meaningful situation in child or adult life. The unit seeks to develop a fusion of mental, emotional, and sensory experience; it proceeds in a physical and social setting that is related to life activities; it is directed toward the accomplishment of a goal that results in some improvement in living. This point of view emphasizes units of human experience, child or adult, as the basis of learning units.

A unit may include such varied experiences as observing, discussing, reading, listening, playing, singing, analyzing, and others. Some units may be carried on largely outside of the four walls of the school, such as the study of an apartment house in the course of construction. Some units in which life activities are introduced may be carried on in school such as painting a chair. Some activities may be carried on in school by introducing actual situations artificially, such as making a bookcase. Some activities may consist chiefly of observing and recording, such as the identification of common birds from specimens or pictures. Some activities, although they utilize actual printed materials, may be entirely mental, such as calculating a fair rental for an apartment from data available.

To discourage the extreme formalization of units, and to encourage teacher-initiative, many curriculum workers place emphasis upon *resource units* as contrasted with so-called *teaching* or *learning units*. This type of guide sets forth many suggestions and possibilities, both as to means of discovering and meeting the needs of pupils within some broad area, and of offering suggestions for appraisal and evaluation. The unit that is prepared for distribution among teachers should be a clear and graphic account of the

total experience, together with any usable aids for the teacher, such as lists of materials and references. Usually, it is a description of activities which have been put into practice experimentally and later revised. Some units, particularly those which are merely narratives of successful projects, are recorded day by day, or after the unit has been completed. As a rule the account emphasizes what the pupils do: their procedure as they go from step to step, their method of organizing the enterprise, the journeys they make, the nature of their preparation out of class, the direction their inquiry takes, the experiments they perform, the reports they plan and execute, the things they build, the exhibits they plan, the phenomena they observe, the research they make, and so on. During this learning activity, the teacher's part is also described; the suggestions he makes, the leading problems he presents, the demonstrations he makes, the guidance he gives; the emphases he makes, the information he contributes, and so on. Thus, a unit of work is essentially a record of things to do, and not an outline of information to be imparted. It is an account of a successful experience that serves as a suggested procedure which an average class under an average teacher may adapt, if it so desires. The unit of work is set up as to the smallest subdivision of the whole curriculum.

A unit of work is contrasted from a lesson plan by the following:

	<i>Unit of Work</i>
Duration	—Lasts several periods, several days, several weeks
For whom?	—Usually designed for general use
Size	—Is usually a full statement
Unity	—Has opportunity for unity
Nature	—Can have a complete life experience
	<i>Lesson Plan</i>
Duration	—Usually covers one period
For whom?	—Written for personal use
Size	—Is usually a brief outline
Unity	—May break off abruptly
Nature	—Is a small subdivision of subject matter

For convenience the two principal types of units are designed as: (a) subject-matter units, and (b) integrative experience units. Subject matter (subject, theme, broad areas of living) units include those organized around usual textbook chapters or topics; units organized around major generalizations, principles, or themes; and units organized around aspects of the environment, such as air, water, sky, or climate.

UNIT PLANNING AND TEACHING

Integrative experience units are less formal and are based more on the immediate interests of pupils or on their immediate purposes, or on a combination of these.

Some subject-matter units draw entirely upon one subject field. Others draw, at least to some extent, upon more than one subject field. Some experience units draw primarily or entirely upon one subject field. However, most experience units involve information from several subject fields. Units which cut across subject fields are taught by one teacher or cooperatively by two or more teachers.

As it is discussed in this statement, a unit consists of purposeful (to the learner), related activities so developed as to give insight into, and increased control of, some significant aspects of the environment; and to provide opportunities for the socialization of pupils. The key words and phrases in that definition are *purposeful to the learner, related activities, insight, increased control, significant aspect of the environment, and socialization*.

Criteria for units include:

1. The unit should involve intimate contact with aspects of social life that are of fundamental significance today.
2. The unit should be so developed as to acquaint pupils with the crucial data, relationships, conditions, problems and the significance for human welfare of the field studies. This requires more than a hasty superficial study of any important topic which is selected.
3. The unit should provide for a large amount of actual experiencing by pupils, and for abundant contact with first-hand source materials.
4. The unit should provide pupils with abundant opportunities for clarifying and enriching the conceptions gained, through various forms of individual and group expression. Creative expression through meaningful dramatization, construction, drawing, sketching, painting, modeling, pageantry, puppetry, music and other means is a significant part of the process of acquiring understanding.
5. The unit should continually stimulate mental activity on the part of pupils. This should reveal itself in the recognition of programs and in their thoughtful consideration. It is revealed in purposing, planning,

executing, and evaluating on ever higher levels.

6. The unit should provide for continuous sharing of purposes, activities, and achievements in an atmosphere of cooperative effort.

No two individuals follow identical plans in developing a unit, and for this reason it seems inadvisable to set down a fixed outline to be followed in reporting work.

A summary of the various patterns used in connection with the outline for a unit has been made by Bawden. He reported the following principal categories: (1) Aims, (2) Preview, (3) Outline of Content, (4) Materials, (5) Suggested Learning Activities, (6) Suggestions for Teachers, and (7) Suggestions for Evaluation.

The principal problem in curriculum development is that of "integration" and "synthesis." While curriculum units are often for purposes of "analysis," the relationship of the unit to the "whole" of which it is a part should be clearly recognized and understood. On the other hand, definiteness requires that the unit be conceived as a body of closely related facts, generalizations, and principles, so organized as to contribute to the understanding of an important aspect of life. The relationship of the unit to larger objectives and experiences should be understood.

It should be possible to present the unit as a whole, in an approach or preview concise enough to give the learner a clear conception of it before he undertakes his study. The aims and purposes should be definitely stated and clearly made, not only to the teacher but also to the pupil.

All pupils should be able to master the essential learnings necessary to attain an understanding of the unit. Because of individual differences among pupils, the unit must contain supplementary and collateral material to allow freedom in adapting the work to the group.

UNIT SHOP. The term "unit shop" may apply to school shops that are (1) of an industrial arts nature or (2) vocational in character. A unit industrial arts shop is a school shop in which only one kind of industrial arts education is given—metal work, or woodwork, but not a combination of these or others. Unit industrial arts shops are commonly found in the larger schools where there are enough pupils to warrant operating a series of shops. The students are usually rotated through the series of unit industrial arts shops at the junior high school level before they specialize in one of them in the senior high school, or transfer to vocational schools or classes.

A unit shop in vocational education is a shop in which a single *trade* or occupational pursuit is taught. For example, a vocational industrial school may have one or more unit shops in machine shop practice, electrical work, aviation sheet metal, air conditioning, and house carpentry. These unit shops are to be distinguished from the unit industrial arts shops just mentioned and also from the "general industrial schools or classes." (See also **GENERAL INDUSTRIAL SCHOOL** and **INDUSTRIAL ARTS EDUCATION**.) F.T.S.

UNIT TRADE SCHOOL. All-day vocational industrial schools, operated in cooperation with the U. S. Office of Education and federally aided, are divided into two types: Type A, which includes Unit Trade Schools and General Industrial Schools (*q.v.*), and Type B, which embraces the General Vocational Schools. Type A schools seek to give thorough and broad training for skilled trades; while Type B schools are for persons seeking to prepare for or advance themselves in, semi-skilled or highly specialized forms of work. For example, persons seeking to prepare for such skilled trades as aviation mechanics, tool and die makers, shipfitting, and machinists, would get their training in a Type A school, if the instruction is to be secured in an all-day vocational school operated on a federally aided basis under the Smith-Hughes or the George-Deen Acts; while men and women receiving conversion training that will enable them to shift from jobs as machine operators in one industry to jobs in other industries, or *vice-versa*, may receive such training under a Type B program in a

general vocational school. (See **VOCATIONAL EDUCATION**.) F.T.S.

UNIT TYPE OF ORGANIZATION—

See **ADMINISTRATION, SCHOOL**.

UNITED STATES COMMISSIONER OF EDUCATION. In the basic law originally creating the Department of Education (now known as the United States Office of Education [*q.v.*]) in the federal government, two general purposes were cited as the function of this new agency, namely, to collect and diffuse educational statistics and facts, and to promote the cause of education in other ways.

To carry out the purpose of the act, Congress authorized an appropriation for a Commissioner of Education and two clerical assistants. From this small beginning, the Commissioner and his regular staff in 1937-38 numbered some 222 persons, exclusive of staff workers for the administration of the Civilian Conservation Corps program and other emergency relief projects.

The act further provided that "it shall be the duty of the Commissioner of Education to present annually to Congress a report embodying the results of his investigations and labors, together with a statement of such facts and recommendations as will, in his judgment, subserve the purpose for which this Department is established."

In the assumption of these general responsibilities the several Commissioners over the years have pioneered in various types of educational endeavors and the important services of the agency have expanded increasingly. The safeguard observed by each of the Commissioners has been to conceive of the functions of the office as those of stimulation and suggestion rather than of compulsion.

The duties of the U. S. Commissioner of Education at the present time deal principally with the administration of three general types of service carried forward with the aid of his staff: (1) research and informational, (2)

advisory and consultative, and (3) promotional.

The Commissioner is appointed by the President of the United States, by and with the advice and consent of the Senate, and his term of office is at the discretion of the President. Since 1929, when the Office of Education was transferred to the newly created Federal Security Agency, the Commissioner has served under the administrator of that agency.

During the seventy-five years of the existence of the Office of Education there have been ten Commissioners, beginning with Henry Barnard (1867-70), then John Eaton (1870-86), N. H. R. Dawson (1886-89), William T. Harris (1889-1906), Elmer E. Brown (1906-11), Philander P. Claxton (1911-21), John J. Tigert (1921-28), William J. Cooper (1929-33), George F. Zook (1933-34), and the present Commissioner, John W. Studebaker (1934-). R.J.M.

UNITED STATES CONSTITUTION AND EDUCATION. The Constitution of the United States contains no direct mention of education, nor does it contain any reference to specific educational functions of the federal government. This omission is understandable in the light of conditions prevailing at the time of the framing of the Constitution. The original states were jealous of their individual prerogatives and rights, and certain of the leading original state delegations were strongly desirous of limiting the provisions of the Constitution to only those matters that

could be considered of primary necessity in binding the mutual interests of all the states.

The Constitution, as formulated, represented a difficult compromise in which matters of less concern to the group as a whole were considered best omitted, or reserved to the individual states by implication. Furthermore, education was considered for the most part a purely local matter in the experience of the delegates and few doubtless even envisioned its importance as of any national interest or concern at the time. As a matter of fact, education during that early period was not often considered a function of the state, for by common consent, except in New England, it remained for religious societies, private individuals, and parents to provide with the means they possessed such education as was felt necessary.

The tenth amendment to the Constitution made clear the reservation to the states of such powers as were not explicitly made the responsibility of the federal government in the Constitution. By implication, then, education has continued constitutionally as a function of each state to be exercised within its discretion.

Gradually, as the importance of education was envisioned by leaders of the times and in spite of rigorous opposition to the changing viewpoint, the early indifference toward it changed to one of increasing interest. Four of the original eleven states soon adopted constitutions including some provision for the establishment of schools; the other seven made no mention of the subject in their constitutions.

With the gradual change in the conception of the function of education in the middle 19th century, and as qualifications for voting were liberalized, more definite statements were written into state constitutions, which indicated its growing importance in the minds of the people. Practically every state constitution adopted or revised since 1865 has included a specific provision relative to the establishment of a system of public schools. A few contain direct prohibitions against the use of public funds for private or parochial schools.

While the Constitution of the United States makes no direct mention of education, the federal government has developed extensive relations to education, beginning with early grants of land for public school purposes and

for institutions of higher education in states formed from the public domain. More recently the government has made grants-in-aid for a variety of specific educational purposes. Many of its bureaus, offices, and departments, especially those recently created, have been given funds for conducting special programs of education. (See UNITED STATES OFFICE OF EDUCATION; FEDERAL AID TO EDUCATION.)

When such actions have been challenged as lacking federal constitutional support, its proponents have generally put forth the "general welfare" clause of the Constitution as supporting authority in lieu of direct constitutional authorization.

Thus, while the Constitution does not obligate the federal government definitely in the matter of public education, there appears to be a growing trend toward a recognition that the federal government has an obligation which it probably will assume increasingly.

UNITED STATES DEPARTMENT OF STATE, DIVISION OF CULTURAL RELATIONS—See CULTURAL RELATIONS, DIVISION OF.

UNITED STATES OFFICE OF EDUCATION. The United States Office of Education was created originally as a *Department of Education* by Act of Congress March 2, 1867; it was changed to the *Office of Education* in 1869; this, in turn, was renamed *Bureau of Education* under the Department of the Interior in 1870; and in 1929 was again called the *Office of Education*. Its original legal functions were limited primarily to educational fact-finding and fact-disseminating and to promoting the cause of education. From time to time numerous added

responsibilities have been assigned to the Office. When the Federal Security Agency was established in 1939, the Office of Education was transferred to that agency.

While there has been considerable sentiment among educators that the United States Office of Education should be given full status as a Department in the federal government with a cabinet secretary at its head, Congress seemingly has been reluctant to take such a step, which ostensibly might lead to ultimate interference by the federal government with the general policy of state and local control and management of public education. Nevertheless, the Office of Education has continued to play an increasingly effective role in educational leadership in the United States through its issuance of annual reports, circulars of information, surveys, and, more recently, bulletins and researches on a variety of timely and interesting educational subjects.

The Office is headed by a Commissioner of Education (See UNITED STATES COMMISSIONER OF EDUCATION) appointed by the President, by and with the advice and consent of the Senate. Its work is divided into administrative divisions covering the fields of Higher Education, American School Systems, Special Problems, Vocational Education and Vocational Rehabilitation (with an assistant commissioner in charge), Comparative Education, Statistical, Editorial, Library and Library Service.

Until February, 1942, the Office published *School Life* as its official journal. For the duration of World War II this was replaced by a modified biweekly publication entitled *Education for Victory*, which deals extensively with wartime activities and the schools.

The Office of Education has no administrative authority over state school systems but possesses certain administrative functions relative to the expenditure of funds appropriated by Congress for vocational education, for co-operation in the vocational rehabilitation of the physically handicapped, for colleges of agriculture and mechanical arts in the states and territories, and for certain wartime emergency training funds.

The Office, since 1926, has conducted five important national surveys: (1) Land grant colleges and universities, 1927-30; (2) Negro colleges and universities, 1927-28; (3) secondary education, 1929-32; (4) education of

teachers; and (5) school finance, 1931-32. The last survey was left incompleated by reason of the failure of Congress to appropriate further funds.

The most important of its continuing publications is *The Biennial Survey of Education* (q.v.), which is a comprehensive statistical and expository review of educational developments in the United States.

More recently, the Office has established services pertaining to Inter-American Educational Relations, the federal forum project (terminated June 30, 1941), public service training, an educational transcription service; has initiated the organization of the United States Office of Education Wartime Commission; and has developed other aids to various wartime programs affecting the schools.

The administrative organization of the Office consists of a Commissioner, an Assistant Commissioner, an Assistant Commissioner for Vocational Education, and an Assistant to the Commissioner. There are a number of consultants, each serving in a specified field, as well as a group of administrative assistants, bearing such varied titles as executive assistant, director, editor-in-chief, and chief clerk. Each of the divisions and services is headed by a chief—except the library of which a librarian is in charge. The library is among the foremost educational libraries in the United States. (See also VOCATIONAL DIVISION, U. S. OFFICE OF EDUCATION.) R.J.M.

UNITED STATES TERRITORIES AND OUTLYING POSSESSIONS, EDUCATION IN. Education in the Territories and Outlying Possessions of the United States functions under a multiplicity of Federal and local controls. There is, it is true, a Division of Territories and Island Possessions in the Department of the Interior, but it can concern itself with only Alaska, Hawaii, Puerto Rico, and the Virgin Islands. Even in these four areas there are wide differences in the policy, financing, and scope of the educational machinery.

Alaska. Alaska, the first to be acquired, has two distinct educational systems. The Territorial system, for whites and "natives of mixed blood leading a civilized life," is legally controlled by the Alaska Legislature. It is administered by a Territorial Board of Education appointed by the Governor with the approval of the Legislature. The Commissioner of Education is, in turn, appointed by the Board of Education. For purposes of local administration there are two general types of schools—those within incorporated cities and those in unincorporated areas. The incorporated city school is jointly financed and administered by the municipality and the Territory, but all responsibility for the establishment, control, and financing of the rural and special schools rests with the Commissioner of Education.

By far the largest share of financial support of Territorial Schools is provided through biennial appropriations by the Territorial Legislature. This is supplemented by the proceeds from a five-dollar school tax levied annually on all able-bodied males between the ages of 21 and 50. A share of the receipts from the National Forest Reserves and the Alaska Game Commission also goes into the school fund. The Federal Government makes an indirect contribution in that 25 per cent of the Federal license monies collected outside the limits of incorporated towns is earmarked for education in the unincorporated areas. The incorporated cities are permitted to levy taxes for school pur-

poses within their own limits. The Territory refunds to each city a percentage of the expenditures incurred, the percentage being determined by the resident school enrollment.

These monies support a system for education through the secondary level. In actual practice, most of the rural schools cannot maintain a high school and the children are required to attend school until they have completed the highest grade in their neighborhood schools or until they have reached their sixteenth birthday.

In 1938 the Territorial schools in incorporated cities enrolled 4,286 children, 26.9 per cent of whom were in secondary school. In the schools outside corporate cities, 2,142 were enrolled during the same year, with only 9.8 per cent in secondary school.

The University of Alaska is supported about equally by the Federal and Territorial Governments. Its chief emphasis is upon scientific and professional training. On the 216 regular students enrolled in 1938-39 less than 10 per cent were in liberal arts. The University indeed reflects the pioneering nature and practical interest of life in Alaska.

Accompanying, but not paralleling, the Territorial School system is the Federal school system for the education of the racially indigenous children. Responsibility rests with the United States Secretary of the Interior. The administrative machinery is centered in the Alaska Section of the Education Division of the Office of Indian Affairs in Washington.

The Federal school system is more comprehensive than is the usual school system, including economic, medical, and social welfare programs for the natives. It is completely financed by Congressional appropriations.

In 1938 the system comprised 98 day schools on the elementary level and two vocational secondary schools. The combined native enrollment in that year was 4,660, of whom 306 were in the two vocational schools.

Accurate ratios between the number of children in school and the school-age population are impossible for the year 1938. The 1930 census sets the ratio at 70.5 for the white population and 48.0 for the native. Estimates of white and native enrollments for 1938 show increases of 26 and 27 per cent, respectively, over the 1930 ratios. The

percentage increase for the total population for the same period was approximately 18. There is no specific information to show how the total increase was divided, but it is obvious that school attendance in both groups is showing improvement.

Hawaii. The most formidable problem of education in Hawaii has been to create out of so many different racial and national elements one American community sharing in a common language and pattern of life. In 1938 the total population of 411,485 was divided into 15.2 per cent Hawaiian, 26.0 per cent Caucasian, 6.9 per cent Chinese, 37.3 per cent Japanese, 12.8 per cent Filipino, and a scattering of 1.8 per cent Korean and others. Within these groupings there are also differences—the Caucasian group, for instance, is composed of Portuguese, Puerto Ricans, Spanish, and continental Americans.

Despite the heterogeneity of the population, education in Hawaii is excellent. It follows a single ladder system from the elementary through the university level. Opportunities are equally available to all races, and children in rural communities suffer no discrimination. There are special vocational classes, and a school for the deaf and blind.

Educational administration is highly centralized. In general, it rests upon enactments by the Territorial Legislature and upon regulations of the Department of Public Instruction. Authority over the Department of Public Instruction is exercised by a body of eight Commissioners, one of whom is the Superintendent of Public Instruction. All are appointed by the Governor, who is himself a Presidential appointee. However, the Territorial Senate must concur in the eight appointments.

One exception to this general centralization is the existence of County Boards of Supervisors, elected by the people. They have responsibility over school funds set aside for new buildings, equipment, repairs, and maintenance.

The Territorial Legislature votes appropriations for teachers' salaries, administrative expenditures, and for the purchase of equipment. Money raised by property taxation in the counties is used for the purchase of sites, and the erection and maintenance of school buildings.

The 1938 public school enrollment of 90,-

880, when arranged by ethnic groups, shows differences in utilization of school facilities. The Hawaiians and Puerto Ricans were well represented in the elementary school, but their representation in the intermediate and high schools was below their relative place in the population. The continental Caucasian group was not proportionately represented on any level. This is due to the large numbers of that group who attend private schools. The proportion of Chinese children in high school was double that of their race in the total population, and the Japanese made up about half the elementary school population and a decided majority in the intermediate and high schools.

Private schools occupy an important place in Hawaii. In 1938 the 110 private schools represented 36.9 per cent of all schools. About 40 per cent of all continental Caucasians in school were enrolled in private schools.

The Oriental Language schools, offering instruction in the Chinese, Korean, and Japanese languages and cultures, are conducted after school hours. There has been some decline in enrollment in recent years, although the Japanese group has maintained a very high percentage of attendance.

Puerto Rico. The most serious problem confronting Puerto Rico is that of a constantly increasing population pressure against its limited resources. This is reflected educationally in overcrowded classes, ill-paid teachers, and a large proportion of school-age population for whom there is no room in school. The 1935 Census reports 571,072 children between the ages of five and eighteen, of whom only 257,845 were in school.

Puerto Rico is largely rural, and school enrollment in the rural areas is much lower than that in the cities. In 1935 the urban schools enrolled 73.9 per cent of all residents between the ages of seven and thirteen while the rural areas enrolled but 56.6 per cent of their residents of the same age. The Commissioner of Education in 1938 estimated that in that year two out of every three persons between the ages of five and eighteen in the rural areas were out of school.

Education in Puerto Rico faces another serious problem—that of language. Bilingualism is the stated policy of the Department of Education, but when more children are out

of school than are in school, and when those who are in school stay only a few years, it is not hard to understand that only 22.9 per cent of the population 10 years of age and over could speak English in 1935.

The people of Puerto Rico have small share in controlling their educational system. The Commissioner of Education, the "key to the entire educational situation," is responsible primarily to the President of the United States and derives his power from the Organic Act.

The Insular Legislature exercises some direction by its promulgation of the school law and by voting the school budget, but the Commissioner is responsible for policy, all courses of study, and the selection of teachers; he also approves all disbursements. In general, the acquisition and maintenance of buildings and equipment are left to the municipalities, and to the municipal School Treasurer-Directors, appointed by the municipal assemblies.

School revenue is derived from three sources—insular, municipal, and Federal grants. The last includes the usual vocational aid plus funds allotted to the Puerto Rico Reconstruction Administration, used mainly for building construction. Funds for the insular appropriations are from customs, Internal Revenue receipts, excise and income taxes. The income of the municipalities is from property taxation.

A review of school enrollment figures reveals an uphill struggle to create facilities. Even though the number of children in school constantly increases, the number out of school increases even faster. In the 15-year period between 1920 and 1935, facilities were expanded to take care of an increase of about 60,000 children. However, in the same period, the number out of school jumped from 240,000 to over 313,000. The distribution of the public school enrollment figures for 1938 seems just as discouraging. Out of a total of 262,250 enrolled, 12,329 (none of whom were in the rural areas) were in grades 9-12. By far the majority (183,806) were enrolled in grades 1-4, and of these, 115,427 were in rural schools.

A brighter side of the rural school problem is shown by the growth of the second-unit rural schools (grades 4-8). These schools, developed in rural areas, serve not only the

children, but the social, economic, and cultural needs of the whole community. The curriculum is equally divided between academic and vocational work of a sort fitted to the needs of the community in which the school functions. In 1938, the second-unit schools reached 11,164 boys and girls in the rural areas.

Guam. The island of Guam, acquired by the United States as a result of the Spanish-American War, has been little known and infrequently visited. The 1938 population consisted of 20,911 natives, and 1,434 others, officers and enlisted men of the United States Navy. The natives are largely Chamorros, a racial mixture of ancient Chamorro with Spanish, Mexican, Anglo-Saxon, and Oriental strains. The culture of the island is predominantly Spanish.

The public school system, established in 1900, used English as the basal language. There is no Chamorro literature, so English was readily accepted.

The President of the United States has always appointed a Navy officer to act as Governor of the island, and to administer all civilian affairs. As Governor, he controls all educational funds, formulates policies, and made all appointments. The Chaplain of the Naval establishment is charged with the administrative functions of public education, aided by a native Superintendent of Schools.

Revenues derived from local taxation by the Naval Government are the chief support of public education. These have been supplemented by Federal funds. In 1937-38, the total cost of education was \$71,192.84, which included \$14,999.58 in Federal money.

Children between the ages of 7 and 12 are required to attend school. In 1938 there were 4,066 children in public school. Illiteracy was very low, being confined almost entirely to those over 21 years of age.

Instruction through the sixth grade is available to all, but entrance to the junior high school is limited to 70 pupils on a competitive basis. The senior high school is a teacher-training institution, and enrollment in the tenth grade is limited to about 25.

There are three schools not financed by the Department of Education. The Guam Institute, supported by tuition fees, enrolled 201 pupils in 1938. The E. S. Root Agricultural School, conducted by the Department of

Agriculture, enrolls about 30 boys annually. The American School is organized to provide for the education of children of the naval personnel. Teachers are selected from among the wives and daughters of that personnel. It is supported by tuition, taxes levied on certain articles in the Naval store, contributions, and a small allotment from the Navy Department. Sixty-three pupils were enrolled in 1937.

American Samoa. Acquisition of American Samoa came about as a result of rivalry among Great Britain, Germany, and the United States in the mid-Pacific. A Joint Commission of the three powers agreed upon a partition in 1899. Great Britain received the Longa Islands, Savage Island, and part of the Solomons. Western Samoa was granted to Germany, and Eastern Samoa to the United States.

American Samoa is a naval station and the Commandant has always been commissioned as Governor by the President. The Navy Chaplain heads the Department of Education, aided by a seven-man Board of Education, appointed by the Governor. The Superintendent of Education is the professional head of the school system, and a native Supervising Principal completes the administrative organization. With certain exceptions, the teachers are natives.

Public schools are supported by the Naval Government treasury. A special school tax is voted annually at the *fono* (the traditional Samoan meeting), and is collected along with the poll tax from all males 18 years of age and over. Because of the family and communal system of land tenure, there is no land taxation.

The Governor reported a population of 12,241 in 1938, of whom 278 were white. This represents a population increase of 21.7 per cent over the 1930 figure, a percentage practically duplicated by the growth in public school enrollment for the same period—from 2,044 to 2,510.

Public schooling is available through the ninth grade. Non-public schools in Samoa occupy a very important place in the educational scene. There are six parochial schools, which, in 1938, enrolled about 480 pupils. These schools have a long missionary history, and two of them offer advanced training in religious work. The rest are elementary.

Another private school, the Feleti School, is financed by the Barstow Foundation. Its aim is to prepare "young men of Samoa in both Samoan and American ways of life so as to prepare them for leadership of their people." In 1938 it had an enrollment of 30 boys, appointed by the Governor. It is a boarding school, with a course of three years following the ninth grade.

There are pastors' schools in all villages, which are open and free to all. Classes are held after school in the Samoan language, and their whole atmosphere is in the Samoan tradition. It is due to these pastors' schools that the percentage of illiteracy (in Samoan, not English) is the lowest of any in all the Territories and Outlying Possessions.

Canal Zone. All activities in the Canal Zone center around the operation and maintenance of the Panama Canal. For this reason all activities are government controlled and financed. The Governor is appointed by the President and is responsible to the Secretary of War. An Executive Secretary is responsible to the Governor for police, fire, school, and civil affairs. A professional educator, appointed by the Governor, is charged specifically with the administration of the school system. Here the problem of local financing does not exist. There are no taxes and no school debt service; practically all funds come from Congressional appropriations.

Schooling is furnished free to all children whose parents reside in the Canal Zone, or whose parents reside outside the Zone, but are citizens of the United States and employed by the Federal Government. Tuition is charged in the Junior College. Thus, public education is free to negro and white, citizen and alien, provided the above conditions are met. Most of the Negro residents of the Zone are aliens, and no machinery exists by which they may become citizens.

In education, as in other Zone activities, there is a sharp line of demarcation between Negroes and whites. They attend separate schools and there are differing facilities. Instruction for whites is available from the elementary through the junior college level. Education for Negroes extends through the ninth grade. Because of this, although there are between two and three Negro children to every white child in the Zone, school enroll-

ment is about equally divided between them. The 1938 enrollment figures were 3,249 white (305 in the Junior College), and 3,099 Negro children.

Virgin Islands. Serious economic conditions and a decreasing population have influenced the educational program in the Virgin Islands. During the last few years, however, both factors have shown an improvement and the schools have prospered accordingly. Illiteracy is practically confined to the group over 21 years of age, and with few exceptions, everyone speaks English.

The Virgin Islands have a civil government, with the Governor appointed by the President. The autonomy of the two municipalities has been maintained since the days of Danish control, and both have their Municipal Councils, which, when called in joint session, constitute the Legislative Assembly.

Thus, public education is mainly a municipal function. There are two separate school systems—one for the Municipality of St. Thomas and St. John, and the other for the Municipality of St. Croix. Each has its own superintendent, appointed by the Secretary of the Interior; and each has its own board of education. Appropriations for education are included in the separate budgets. These, however, have been, and are insufficient. Federal appropriations are made to cover deficits, and some Federal funds have been used for school construction and repairs.

Both municipalities maintain schools on the elementary, junior high, and senior high school levels. However, a relatively small proportion of the school population enjoys the privileges of senior high school. In 1938, out of a total enrollment of 3,374 in both municipalities, only 5.3 per cent were in the senior high school.

Private schools hold an important place in the Virgin Islands. They are denominational, and in 1938 enrolled 1,377 pupils, or 29 per cent of the total school population.

The limited resources and population of the islands make the maintenance of a college impossible. Some students do attend the University of Puerto Rico, and a few municipal scholarships are available for students to study in the States.

UNIVERSE—See **SAMPLING**.

UNIVERSITY EDUCATION. In the United States the university is typically an institution of higher education comprising an undergraduate college of liberal arts and sciences, professional units or colleges, and a graduate division that offers programs beyond the baccalaureate and the first professional degrees. However, some schools traditionally have borne the label of university without fulfilling this definition, and in some instances offer little instruction beyond the scope of a liberal arts college. On the other hand, certain schools without the designation of "university" are offering graduate or advanced professional programs of instruction. There are more than two hundred chartered American "universities," although not all qualify under the definition given above.

The diverse functions and complex structure of the modern university are indicated by its varied subdivisions. In addition to the undergraduate college of liberal arts and the graduate school, the university may include one or more of the following professional schools, colleges, or divisions: agriculture, architecture, business administration, dentistry, education, engineering, forestry, home economics, journalism, law, library, medicine, music, nursing, pharmacy, social work, speech, theology, and veterinary medicine.

Colleges and universities are controlled by boards of trustees or directors, in some instances self-perpetuating, but more commonly elected or appointed. Board membership for church-related colleges may be determined by relationship to some religious body. For state universities the board may be elected by the voters or appointed by the governor. In recent years certain states have placed all state institutions of higher education under one controlling board, creating in effect a state system of higher education. The trustees elect a president, appoint faculty members on recommendation of the president, formulate

governing regulations and policies, and supervise the funds and property of the institution.

Entrance to the undergraduate college and to some professional divisions of the university is based primarily on graduation from a recognized secondary school, while certain other professional colleges require for admission a period of undergraduate preparation. Entrance to some colleges of medicine and law is based on four years of undergraduate college work. The length of the curriculum of a professional school or college, like that of the liberal arts college (*q.v.*), is usually four years.

At least six major developments have characterized the innovations of higher education during recent years, especially liberal-arts education:

1. Deviations from the four-year homogeneous unit to permit graduation in less than four years.

2. Reorganization of content to emphasize fields of learning.

3. Adoption or increased development of honors work, the tutorial method, and general examinations. Honors work is intended as a stimulus to the superior students of the junior and senior years, through individualized or tutorial instruction, usually with specialization in a particular department culminating in a comprehensive examination at the end of the college program.

4. Adjustment of the curriculum to the individual student.

5. Application of the principle of learning through experience.

6. Use of achievement tests and substitutes for course credits. (See **GRADUATE EDUCATION**; **HIGHER EDUCATION**; **MUNICIPAL COLLEGES AND UNIVERSITIES**; **STATE COLLEGES AND UNIVERSITIES**; and such articles on Professional Education as **LEGAL EDUCATION** and **MEDICAL EDUCATION**.)

UNIVERSITY EXTENSION. The expression *university extension* is used to designate a variety of ways of extending the educational services of higher institutions to the general population, including correspondence courses and class instruction on or off the campus for persons not registered as resident students of the institution. State universities and institutions in large metropolitan areas have been particularly active in the establishment of off-campus centers of instruction. The services of university extension are a part of the much larger field of instruction known as adult education (q.v.).

Extension courses with academic credit are similar in form and content to those offered for resident students. The relatively informal educational activities of university extension centers reach both adult and youth groups, and deal with a wide range of problems (for example, agriculture, home economics, recreation, health, civic affairs, and industry) through lectures, classes, instruction by mail, library loans, visual aids, school contests, conferences, institutes, demonstrations, short courses, forums, advisory services, publications, and radio. Extension classes are usually taught by members of the resident faculty, although specialists from the professions, trades, and industry are employed for particular types of instruction. A few universities have a special faculty group that devotes full time to extension duties. C.V.G.

UNIVERSITY LIBRARIES — See LIBRARIES, UNIVERSITY AND RESEARCH.

URUGUAY, EDUCATION IN. Uruguay, about equal in area to North Dakota,

is the smallest of the South American countries. Located in a temperate climate at the mouth of the *Rio de la Plata*, it is mostly made up of flat, green pasture land, and is open to the east. Ninety-five per cent of its 2,300,000 inhabitants are white, the majority being of Latin stock. Thirty per cent live in the cities, mostly in Montevideo. Industry and cattle raising are the chief economic enterprises. Only 5 per cent of the arable land is cultivated. Besides this, there are some mining and forestry, and a considerable income accrues from the beaches, which attract neighbors from Argentina in great numbers. After the *Independencia* the security of Uruguay was threatened constantly by the ambitions of its two powerful neighbors, Argentina and Brazil, and by its own bloody inner dissensions between conservatives and radicals (*Blancos* and *Colorados*). But in the last forty years the country has settled down peacefully. Credit for this goes largely to the enlightened activities of President José Battle y Ordóñez (1903) and to the *Colorado* government that has been in power since that time. Uruguay is today a center of democracy, the staunchest supporter of Pan-American solidarity, and has the most progressive economic and social legislation of the South American continent. The paternalistic state is itself owner of basic enterprises and guarantees the social security of all its citizens.

Such conditions could foster a democratic and progressive system of education. The liberator of Uruguay, the *Gaúcho* Artigas, founded the first secular school as early as 1811. The next step arose, as in other South American countries, from the educational activities of James Thompson, the Scotchman, who with the support of the authorities (at that time the Portuguese from Brazil) introduced the Lancastrian system in 1821. The common school came into existence under the influence of Horace Mann. It was created by his ardent disciple, the *Horacio Mann* Uruguayo, José Pedro Varela, and found expression in the Education Act of 1877. It brought about centralization of educational administration, inspection of the private schools, free and compulsory education, and drastic limitation of religious education in the public schools. Religious education in public schools disappeared completely when the constitution of 1917 pronounced the separation

UTILIZATION OF SCHOOL BUILDINGS

tion of state and church. Owing to the necessity of equalizing educational opportunity in the urban and rural areas, educational administration is today becoming still more centralized under different democratically organized councils for the different branches of education. Private, state-inspected education prevails only at the kindergarten level, in twelve out of a total of thirteen kindergartens. Only 12 per cent of the elementary and about 15 per cent of the secondary school population attend private institutions. In spite of very progressive legislation, lack of schools accounts for the fact that only 9 per cent of the population can attend, and that the problem of illiteracy (estimated from 20 to 35 per cent of the adult population) has not yet been mastered. Public and private agencies are making outstanding efforts in this direction.

The compulsory school age is from six to fourteen in elementary schools and extends for three more years (nine hours a week) in a vocational continuation school. The two last years of the elementary school have a vocational bias. Since 1917 part-time vocational schools for all the existing trades have been established for boys and girls. There is now also one full-time vocational school with 240 students who enter at the age of twelve after six years of primary school. All the other postprimary or secondary schools (about 30 with about 11,000 students), which were formerly under the authority of the university, follow almost completely the European pattern. The twelve-year-olds go through the same rigid academic course for five years. The sixth year has six divisions. Of these, five are professional and lead to the respective university schools; the sixth has a commercial bias. But all these six groups have a common academic core of fourteen hours weekly, i.e., half of their total schedule.

The great majority of the teachers are women. They are trained in two normal schools in Montevideo and three in the provinces. These have a general curriculum of four and a professional curriculum of three years, with practice teaching in the last two years. Special training for secondary and special teachers is planned, but does not yet exist.

The university in Montevideo was founded in 1847 in the positivist spirit of the time and still lacks a philosophical faculty. It enjoys self-government, with the faculty councils elected not only by and from the professors but also by and from the students.

This progressive country has followed progressive methods throughout the school system since it instituted its new educational program in 1928. In this respect it is indebted to its leading educator, Vaz Ferreira, and to three private experimental schools. Two originated in 1925 under the influence of a visitor from Colombia, A. Nieto Caballero. Like his *Gimnasio Moderno* in Bogota, they adopted the methods of Decroly. Sabas Olaizola directs the best known of them at Las Piedras.

If we add that the social and health services connected with the school are expanding from year to year (meals for the needy, vacation colonies, etc.), it is realized that Uruguay must be ranked next to Argentina and Chile on the scale of educational achievement among the South American countries.

V

V—See VARIATION, COEFFICIENT OF.

VACATION BIBLE SCHOOL. The Vacation Bible School plan is used by many churches to provide religious education and other worthwhile activities during the summer vacation period for children of from five to fourteen years of age. The usual schedule of the school is a two- to three-hour session, five days a week, for a period of from three to six weeks during July and August.

Although religious instruction forms a part of the program of the Bible school, games, dramatics, and arts-and-crafts activities account for most of the time spent.

The school is conducted frequently under inter-church auspices, resulting in a curriculum less denominational in character than that of the parish church school. W.V.N.

VALIDITY, TEST. The *validity* of a test is determined by the extent to which it measures what it purports to measure. This, if a test is supposed to measure ability in history, the score obtained by the pupil should be an indication of his knowledge of history, not of his ability to read.

Several methods are commonly used in validating a test. According to one method, the content of local and state courses of study and textbooks in the field is analyzed and the relative frequency of occurrence of topics or items determined. The test can then be designed to include those items which are given most weight in the materials analyzed. The major weakness in using this method of content validation lies in the fact that present practice, even though it may be faulty, determines the materials included on the test. Moreover, although a test may be valid in so far as curriculum practice for the country as a whole is concerned, it may be lacking wholly in validity for a school that emphasizes entirely different materials.

A test also may be validated by using statistical methods. Techniques commonly employed involve correlating the scores on the

test with some criterion measure, such as school marks, other tests in the field, or ratings by experts. Thus, a psychologist who has devised a group test for measuring intelligence may correlate the results on his test with the scores which the same examinees receive on the Stanford Revision of the Binet-Simon tests; or a test constructor who has prepared a standardized test for measuring a trait such as leadership may compare students' scores on his test with the ratings given the same students by their teachers and by psychologists. Underlying the use of such procedures for establishing the validity of a test is the assumption that the criterion measures are themselves valid. If, for example, the ratings of leadership as given by teachers and psychologists are not valid, any test which has a high correlation with these ratings is also likely not to be valid. J.J.

VANDALISM. The term *vandalism* is used to describe the ruthless destruction or defacement of property. Most vandalism occurs in connection with public property, such as parks, playgrounds, recreation centers, and school equipment and buildings. Examples of such depredations include smashing windows and stripping bark from trees and shrubs. School offenses usually comprise writing on or carving desks, drawing pictures or writing words of an obscene nature in toilets or on buildings, cutting pages and illustrations from library books and magazines, or defacing buildings or monuments belonging to rival schools.

Most of this destructive activity is said to be committed by boys between the ages of 15 and 21. It appears, therefore, that one basic cause of this behavior is the desire for adventure, coupled with the gang spirit so characteristic of adolescence. In many instances no wholesome outlet for natural activity is provided and vandalism becomes the major means of "having fun." In a few cases hatred of school or of certain individuals may be the motivating factor.

VARIABILITY

In coping with this problem, it is essential that a sense of property rights and of responsibility be developed in early childhood. The feeling should be created that public property belongs to all of us, and, therefore, everyone is responsible for its protection and care. The guidance of gang activities into acceptable channels through providing supervised recreation, the organization of high school students into protective groups, and community efforts to afford opportunities for legitimate adventure (e.g., municipally-supervised Hallowe'en carnivals) should aid greatly in the reduction of vandalism. If teachers would place less emphasis upon elaborate note books, the temptation to mutilate encyclopedias and books might be lessened. The creation of more wholesome sex attitudes and better supervision of toilets might prevent some of the obscene defacement referred to above.

R.V.M.

VARIABILITY. Since the individual items in an array of measures (such as the scores made by a class on an arithmetic test) usually differ from one another, it is desirable to have some measure of the extent of the scatter. The degree of homogeneity or heterogeneity in a frequency distribution is variously referred to as *dispersion*, *variability*, *deviation*, *spread*, and *scatter*.

Range. The *range*, one of the simplest but least adequate of all measures used to express quantitatively the variability of a distribution of scores, is the difference between the highest and the lowest scores. Since it is dependent only upon the two extreme individuals in the group and since it tells us nothing of the spread of the scores between these two extremes, the range is not a very meaningful measure, although it is easily understood by the layman. Thus, all people know what is meant when we say that the teachers' salaries in a given school system range from \$1,200 to \$3,700 a year.

Semi-interquartile range. (Also called *quartile deviation* or *Q*). The semi-interquartile range is one-half the distance between the 75th and the 25th percentiles. Like all other measures based upon percentiles, the semi-interquartile range does not take into consideration the value of each individual score within the distribution. Two distributions may show the same semi-interquartile range, and yet the

outlying scores in one distribution may be far more extreme than in the other.

Average deviation. The average deviation is the arithmetic mean of the differences between all scores and the central tendency (usually the mean), disregarding algebraic signs. The average deviation is superior to the range and the semi-interquartile range because all the items in the distribution help determine the size of the average deviation. Its interpretation is similar to that of the standard deviation.

Standard deviation. The standard deviation (σ) is a measure of variability employed extensively in technical statistics. The standard deviation is the square root of the mean of the squares of the deviations of the variates from the mean of the array. In the computation of the standard deviation, the distribution of all scores affects the size of the standard deviation, but the formula gives increasing weight to scores as they vary more and more from the mean of the distribution. The formula for computing standard deviation and the steps to be followed in making the computations are included in all standard textbooks on educational statistics.

The standard deviation computed from a small sample tends to be a little smaller in numerical value than that computed from a larger sample drawn from the same population; and it is at its maximum when taken from the whole number of variates which constitute the universe from which the samples are drawn. This last is called the "population value". In most statistical practice this "true" or "population" value cannot be computed because the number of variates in the universe is infinite and their mean is unknown. It can be inferred, however, by using a modification of the usual formula for computing the standard deviation.

It is a long-standing practice to designate the standard deviation by the lower-case Greek letter sigma, and to represent the corresponding "true" value by the sigma with a tilde over it ($\bar{\sigma}$).

In the opinion of the present writer, the standard deviation is a very awkward *descriptive* statistic for variability. It comes very naturally and importantly into theoretical statistics, and into the calculation of correlation coefficients and measures of reliability, because it is a by-product from fitting

by the principle of least squares, and from these uses it has come to be employed very extensively also as a descriptive statistic to express the variability of a set of scores. But for this purpose the *average deviation* would serve much better, especially when talking to laymen, because it has a more straightforward meaning and is only a little less reliable than the standard deviation. However, people who work much with technical statistics soon come to attach rather vivid interpretations to standard deviations: they infer, for example, that if the mean of the reading ages of a class of pupils is 9.4 and the standard deviation is 1.4, about $\frac{2}{3}$ of the pupils (68.27 per cent of them if the distribution is normal) will have reading ages somewhere between 9.4 ± 1.4 , (or 10.8) and $9.4 - 1.4$ (or 8.0); a little over 95 per cent will probably have reading ages between 12.2 and 6.6 (which is $\pm 2\sigma$'s, while nearly all of them (99.7 per cent) may be expected to have reading ages between 13.6 and 5.2, which is between the mean and plus or minus three standard deviations. Of course, similar interpretations could be made in terms of the average deviation; but statistical workers are so fully committed to the standard deviation, even as a descriptive statistic, that there is little present prospect of change.

Standard deviation is used also to describe the extent of variation in statistics due to sampling fluctuation, though here the term *standard error* is most often used instead of *standard deviation*. Formulas have been derived for inferring the standard error resulting from fluctuation of sampling in the case of nearly all the statistics we know how to compute. (See RELIABILITY.)

The following distribution of scores on Part II of the *Otis Classification Test* for 88 pupils in the third grade allows comparison of the several measures of dispersion.

score	f
30-34	3
25-29	8
20-24	18
15-19	30
10-14	17
5-9	10
0-4	2

Computed according to the definitions above and the usual formulas, the standard deviation of this array of scores is 6.57, the average deviation is 4.89, and the semi-interquartile range (Q) is 4.5, while the range

(from the lower border of the first interval to the upper border of the last) is 35. The reader should observe the relative magnitudes of these variability measures. In a perfectly normal distribution A. D. is .7979 times as large as the standard deviation, Q is .6745 times the standard deviation, and A. D. equals 1.1830Q. (See also VARIATION, COEFFICIENT OF.) C.C.P.

H. SORENSON, *Statistics for Students of Psychology and Education* (McGraw-Hill Book Co., New York, 1936).

VARIABLE ERROR. A *variable error*, or *chance error*, results when obtained scores for individual pupils may equally well be above or below the theoretically true values. Variable errors result from the operation of such environmental and psychological factors as different testing conditions, different degrees of pupil interest and attention, and different types of pupil attitudes toward the test and examiner. The direction of variable errors (whether an individual score is too high or too low) can seldom be determined, but if the number of students being tested is sufficiently great the effect of variable errors on the average for the group is usually negligible. (See CONSTANT ERROR.) J.R.G.

VARIATION, COEFFICIENT OF. A measure of *relative* variability as distinguished from *absolute* variability. If we ask, "Which group is more variable in height, new-born boys or twelve-year old boys?" the answer would depend upon whether we are thinking of amount of variability as measured by the standard deviation (or average deviation, or semi-interquartile range) of each group, or whether we are thinking in terms of variability *for their size*. The twelve-year-olds have greater possibilities of variability because of their greater average height. In comparing the two groups on a common basis we would take into consideration their mean height. The coefficient of variability is computed by the formula 100 S.D./M , or one hundred times the standard deviation divided by the mean. The symbol is V . V therefore tells us what per

cent the standard deviation is of the mean. One group may be absolutely more variable than another yet, relatively to the mean, less variable. *V* has limited usefulness in that the measuring scales must possess the same unit and the measurements must be in reference to an absolute zero point. This disqualifies most test scores for the purpose of computing *V*. (See VARIABILITY.) J.P.G.

VENEZUELA, EDUCATION IN. Venezuela has a territory as large as Germany, England, Belgium, and Holland combined. In the west are the high Andes and in the east the wide plains of the Orinoco. This large country is only sparsely settled by a population of about 3,500,000 people. The great majority (about 80 per cent) is *mestizo*. Health conditions, owing to climate and undernourishment, are miserable, but Venezuela, which has been exploited by the few, is rich in resources. It is the third largest producer of oil in the world, and until World War II was without any public debt. The flood of foreign currency connected with the oil business made prices soar, and this factor added to the scarcity of homegrown food increased the abject poverty of the masses. Only since 1937 has the government made the attempt to extend agriculture and cattle raising and to improve the working conditions. Until 1936 this birthland of the great liberator Bolívar was in the hands of successive ruthless dictators until finally, in 1909, it became the prey of the most cruel of all, Juan Vicente Gomez. Only after his death in 1935 could Venezuela start its history as a modern nation. Most of the credit for the great progress the country has made since 1935 goes to the successor of Gomez, Lopez Contreras, and after 1941 to President Medina, who continued the work initiated by Lopez.

Under such conditions as have existed in Venezuela in the past, education could hardly develop. Although Lancaster had introduced his system there in 1820 and although free and compulsory education was decreed in 1870 by the dictator Guzman Blanco, the continuous civil wars and finally the rule of Gomez prevented any progress. The new government understood clearly that building democracy in such a backward and exploited country was a work of education. But there was at that time hardly any budget—2,500,000 inflated *bolivares* under Gomez—; there

was neither efficient administration nor adequate buildings; there were only 2,161 primary schools, attended by 19.9 per cent of the 689,288 school-age children; and few of the 1,900 teachers were trained for their work.

Today 22,000,000 gold *bolivares* are spent by the centralized administration, the Ministry of Education in Caracas. The ministry recognizes that the needs of the mostly rural population—the 90 per cent illiterate adults, as well as the children—have to be met first. To obtain quick results a special extension division has been created in the Ministry of Education, which uses the modern means of mass education: motion pictures, radio, and correspondence courses. This activity is partly on the elementary level, and partly aims at the rehabilitation of teachers in service. Meanwhile a deeper basis also has been established. The following three model institutions promote rural education: (1) The rural school, *Tamanaco*, where stress is not on the 3 R's but primarily on the skills which will enable the boys and girls to reconstruct their rural environment. Land and animals, implements, and laboratories are provided, and the pupils learn by doing. (2) The rural normal school, *El Macaro*, whose course is three years. The first year teaches the subject matter to the sixth grade; the second, rural techniques; and the third gives training in education. (3) The Central Rural Mission. The missionaries are educated at *El Macaro*. They are teachers in service. It is their duty to work as rural teachers of the new type in districts which have not been reached by education, to help liquidate illiteracy, to disseminate health information, and to render health service. The same spirit animates three great educational ventures which already extend beyond the described immediate needs: (1) The model school, patterned after Lincoln School of Teachers College, opened in Caracas in 1939, which is attended by 1,300 children and includes all levels from kindergarten to high school. All the rooms necessary in a modern school and all the appliances (for example, a radio in every class) are provided. All the activities, from the care of animals to the theatre, the modern dance, and the printing of a newspaper, are included. The school's first director was Sabas Olaizola, the well known Uruguayan educator. Valerio Ostos, a young Uruguayan, is now in charge of the school, whose staff

also includes some American teachers. (2) The *Institut Pedagógico*, located in an imposing building with air-conditioned rooms, athletic field, etc. Grade teachers as well as high school teachers are trained here in three-year courses. A complete secondary school for practice teaching is on the premises. (3) The *Colonia de Vacaciones of Catia la Mar*. Rotating groups of 600 boys and girls each are sent there for a fortnight from Caracas to learn and to enjoy healthy living.

The secondary schools still follow the academic European pattern. They have a first four-year cycle of required subjects and a second two-year cycle which has three university-preparatory divisions: philosophy and letters, physical sciences and mathematics, and biological sciences. The creation of a technical council in the Ministry of Education seems to indicate that with the growth of industry more attention will be given to post-primary, nonacademic education. The Universities of Caracas and Merida have not yet been reformed.

Progress during the last few years has been extraordinary. There are three times as many schools and four times as many teachers as in 1935. Moreover, the central importance of modern democratic education has found recognition in the very progressive Education Act of 1941.

VERBAL ILLUSTRATIONS. Of all the words in the teacher's vocabulary, possibly the two most important ones are *for example*. . . . They take such an abstract statement as ". . . the judiciary interprets the laws" which the high school student repeats almost like a mystic formula because it adds percentage points to his examination mark and translate it into a point of view which the adolescent recognizes as a part of the foundation of our way of living. The effective use of illustrations, and they may be verbal as well as visual, makes clear what would otherwise be vague, and makes vivid and forceful what would otherwise be prosaic.

So much attention has been given to the use of visual and auditory aids to learning

(See AUDIO VISUAL AIDS, AUDITORY AIDS, MOTION PICTURES IN EDUCATION, REALIA, and RADIO EDUCATION.) that too little thought is given to the contribution which such other types of illustrations as dramatization and verbal illustrations can make to the learning process. By acting out the situation, the teacher can demonstrate the distinction between *saunter* and *walk* more clearly, more vividly, and more quickly than he can explain the distinction by words alone. Similarly, a well-chosen verbal illustration can make concrete and comprehensible so abstract a principle as the law of diminishing returns.

Although all teachers are aware of the usefulness of verbal illustrations, which need no mechanical equipment or elaborate preparations, few use them with maximum effectiveness. It is typical of educational thinking that there should be so many research studies dealing with the uses and values of motion pictures in education and so little research concerning the more widely used verbal illustration. As a result, the available published material relating to verbal illustrations reflects the influence of expert opinion rather than of objective investigations.

The suggestions which have been presented by those who have studied the use of verbal illustrations all indicate the desirability of having the teacher select and organize the verbal illustrations in advance of the class meeting. Though it is impossible to predict everything that will be said during a classroom discussion, the teacher should be able to anticipate the major concepts that will probably play a major part in the discussion. Some experienced teachers may be able to think of appropriate illustrations on the spur of the moment, but all teachers will probably be able to think of better illustrations if time and thought are given to the process of selection. This emphasis on the teacher's selection of illustrations need not imply that all illustrations should be given by the teacher. Illustrations which come from students help clarify their thinking and may reveal inadequacies of understanding or misinterpretation. Thus the social studies class which is studying the problems of mass production will see the problem more clearly if they are made familiar with several illustrations of mass production. The students themselves should be encouraged to suggest additional instances

VERTICAL ORGANIZATION OF SUPERVISION

of mass production with which they are familiar.

Since the purpose of the verbal illustration is to make a concept vivid and clear, it is obvious that the illustration must be on the pupil's comprehension level and within his range of experience. Illustrations of technological unemployment are best when they deal with occupations familiar to the student. Thus the explanation of the way in which the installation of automatic steel rolling machines reduced the need for steel workers may not be as meaningful to students living in a commercial city as would an illustration of the way in which the use of paint spraying machines reduced the number of painters needed. Children who think that only ignorant and selfish textile workers fought against the introduction of the power loom may understand this reaction better if they think in terms of local and contemporary parallels. It is, therefore, hard to find an illustration of any concept that has universal appeal and significance. To be most meaningful, the illustration must be planned for the specific group of students for whom it is intended.

Good verbal illustrations are usually concrete rather than abstract. The mythical purchases which Mr. A. makes from Mr. B. may not be as vital an illustration of economic principles as the purchases which these students make at the school bookstore. A realistic illustration, if possible a true instance, is usually more challenging than a hypothetical one. All bookkeeping teachers, for example, know how much more interest is aroused when the illustrative material is a page taken from the real ledger of a going concern instead of a reproduction of the hypothetical concerns usually described in textbooks. Similarly, a verbal illustration taken from a real business transaction is usually superior to an abstract illustration which applies to business generally.

Though the verbal illustration is a useful aid to learning, its value may be reduced if too much importance is attached to it. Verbal illustrations are means to ends, not ends in themselves. Obviously, no illustration should be so long or so involved that it takes the student's mind away from the major problem at hand. Similarly, the illustration may sometimes be so interesting that the students ignore the point it was intended to clarify.

Telling a story is an effective method of vesting the various school subjects with an air of reality by enriching them with verbal detail and meaningful illustrations. Thus the account of Pasteur's search for the factors that caused wine to turn sour adds to the students' interest in, and understanding of, the process of pasteurization. This does not mean that all teaching should be done by the story-telling method. As Horn points out in his *Methods of Instruction in the Social Studies*, the story-telling method as the principal device for teaching has been largely discredited, even in the elementary school. Oral instruction, including story-telling, is nevertheless a useful teaching procedure on all levels. It may be used to introduce a new topic, to illustrate a particular point, or to sum up a lesson.

It is well to keep in mind that, while the use of story-telling adds interest to almost any topic, it must be well done to be effective. The teacher who talks too slowly, fails to simplify his language to suit his audience, and who uses all the class time in his own oral presentation without allowing the pupil an opportunity to ask questions or to express his ideas, runs the risk of making his subject dull and monotonous. The effective teacher tells his story with enthusiasm, with a good sense of the dramatic, with appropriate gestures, and with a sense of proportion of time. Thus presented, good oral presentations give pupils experience at learning through listening, a skill much needed in these days of radio. The verbal presentation may also save time for the class, for the teacher can thus set the stage, clarify hazy ideas, and add significant detail. The results of most experimentation in oral learning versus the recitation and other methods indicate that the better pupils profit by extended oral presentation while the less able pupils neither like, nor learn much from lectures.

VERTICAL ORGANIZATION OF SUPERVISION—See SUPERVISION OF INSTRUCTION.

VETERINARY EDUCATION. The standards of veterinary education in the United States have advanced greatly during the third and fourth decades of the twentieth century and especially in the period since 1930. These changes have followed the pattern of those that occurred in medical education somewhat earlier. When the U. S. entered the first World War there were about twenty-five veterinary schools, of which more than half were proprietary. By 1920 most of the proprietary schools found it impossible to meet advancing requirements of veterinary practice laws and were compelled to discontinue, leaving this educational field to tax supported and endowed institutions. In 1927 the last proprietary veterinary school closed its doors. Of the ten accredited schools now operating in the United States, nine are state supported and one is supported partly by endowment and partly by tax-raised funds.

The American Veterinary Medical Association and the U. S. Department of Agriculture are the two principal accrediting agencies for veterinary schools in this country.

Through its Committee on Education, the American Veterinary Medical Association collects data from the schools and periodically inspects their physical facilities and teaching methods. The ratings of the Association are accepted by the U. S. Army and by the licensing boards of many of the states. Some states, e.g., New York, do their own accrediting. The schools that are approved by the Association at present (1942) are as follows:

Alabama Polytechnic Institute, School of Veterinary Medicine, Auburn, Ala.; Colorado State College, Division of Veterinary Medicine, Fort Collins, Colo.; Cornell University, New York State Veterinary College, Ithaca, N. Y.; Iowa State College, Division of Veterinary Medicine, Ames, Iowa; Kansas State College, Division of Veterinary Medicine, Manhattan, Kansas; Ohio State University, College of Veterinary Medicine, Columbus, Ohio; Michigan State College, Division of Veterinary Medicine, East Lansing, Mich.; Pennsylvania, University of, School of Veterinary Medicine, Philadelphia, Pa.; Texas Agricultural and Mechanical College, Division of Veterinary Medicine, College Station, Texas; and Washington State College, Division of Veterinary Medicine, Pullman, Wash.

The U. S. Department of Agriculture, which

is the largest single employer of veterinarians in the country in its meat inspection, quarantine, and field inspecting divisions, promulgates regulations governing entrance to veterinary-inspector examinations given by the U. S. Civil Service Commission in which a list of approved schools is given. At present this list includes the active schools listed above, and others which have existed in the past but are no longer operating.

With one exception, all of the active schools on these approved lists require a minimum of one year of satisfactory college work for admission. The exception, the University of Pennsylvania, requires two years. All of the schools require four years' work for the professional degree; therefore every graduate now has at least five years of college work. The professional degree, granted to those who complete their courses successfully, is Doctor of Veterinary Medicine (D.V.M.).

All states now have licensing boards which conduct their own examinations and every practitioner must hold a license in the state in which he practices.

Until about 1930, admission to most veterinary schools was easily obtained by those who wished to enter the profession. This situation has changed radically in recent years and at present only a small percentage of those who wish to enter the profession are able to obtain admission to the approved schools. Admission is on a highly selective basis, scholarship, previous experience with animals, and personal qualities being considered in making the selections. Women are considered by most of the schools, but few are admitted at present.

The curricula of the approved veterinary schools differ in details but are basically alike. The pattern of instruction is like that of the medical schools, the first two years being devoted to the basic, preclinical subjects—anatomy, histology, physiology, physiological chemistry, bacteriology, parasitology, pathology and material medica—and the remainder of the course to the applied subjects—medicine and therapeutics, surgery, obstetrics, and clinical practice. The emphasis on subject matter differs somewhat from that in the curricula of medical schools. Parasitology, for example, is a much more important subject in veterinary medicine than it is in human medicine, and consequently is treated

much more thoroughly. Greater attention than in medical schools is given, also, to food hygiene, with particular reference to meat and milk. On the other hand the veterinary curriculum lacks instruction in psychiatry.

There is no period of internship in veterinary medicine as there is in human medicine. Accordingly an attempt is made to give students as much actual experience as possible in the diagnosis and treatment of diseases by medicinal and surgical means in their clinical work. Although practice laws do not require it, young graduates are encouraged to work at least one year with established practitioners before entering practice for themselves, and a considerable proportion of all graduates follow this course. VIRGIN ISLANDS, EDUCATION IN

—See UNITED STATES TERRITORIES AND OUTLYING POSSESSIONS, EDUCATION IN.

VISION. The simplest approach to the study of children's vision is the observation of children in the classroom and on the playground. In these situations the teacher can note signs of eyestrain and visual difficulty: watery eyes; red, swollen, or encrusted eyelids; styes; lack of coordination in using both eyes; errors in reading letters and figures similar in form; abnormal positions of holding a book; squinting; frowning; etc. From parents the teacher may obtain information about illnesses which may have affected vision, and also about headaches, nausea, dizziness, sensitivity to light, and blurred vision. If medical or nursing aid is not available, the teacher may learn to give the Snellen test with precision and accuracy. More difficult is the interpretation of the findings of the eye examination and the task of getting the defects corrected. Children having visual acuity of 20/30 or less in either eye and who consistently present symptoms of visual difficulty regardless of visual acuity should be referred for further examination and treat-

ment to an eye physician (ophthalmologist).

There are many educational problems arising from defective vision, not all of which are obvious. With some children, defects of vision interfere with school work. In other instances no relation between visual defects and scholastic marks is evident, but strain and discomfort may nevertheless result from the child's attempt to compensate for the visual handicap. It has also been found that children with certain visual defects have more difficulty in learning to read. On the playground, clumsiness and inaccuracy may be due to visual defects. The good adjustment of school children obviously requires systematic and adequate eye examination, correction of remediable defects, provision of activities suitable to the visual maturity of children, control of lighting conditions, and special classroom adjustments for pupils with poor vision.

Irregularities or disorders of vision are many: they may occur in any portion of the visual mechanism, and may be of congenital, nutritional, traumatic (physical injury), or functional (psychogenic) origin. Thus, there may be a loss of transparency in the refracting media such as a *cataract* on the lens, or some similar deposit on the cornea or in the interior of the eyeball. The eyeball may be too short, or too long, or the curvature of the cornea may be irregular, as is the case respectively in congenital far-sightedness (*hyperopia*), near-sightedness (*myopia*), and *astigmatism*. The power of accommodation may be weakened, as normally happens after ten years of age, resulting eventually in the indistinct vision of *presbyopia*. The two eyes may not converge properly, causing the various types of *phorias*, or squint-eyedness. The retina may have an insufficient number of cones, producing *color-blindness*, the red-green variety of which is common to three or four per cent of the male population. The rods may be blocked in action through a vitamin A deficiency so that the individual becomes afflicted with *night-blindness* and is unable to become *dark-adapted* and to see appropriately in the dark. An injury to an optic nerve before its point of crossing may result in blindness in one eye, but an injury between the crosspoint and the brain may give rise to the special condition of half-blindness in each eye, known as *hemianopsia*. Lesions in the

optic cortex may cause total blindness, or only losses in some small part of the visual field, or they may merely impair visual memory—all depending upon the extent and the locus of the lesion. Finally, visual disturbances of pure psychogenic origin may also occur. There may be complete hysterical blindness in one or both eyes, or simply an extreme narrowing of the visual field as in *tunnel vision*, or just a widespread fear and avoidance of light as in *photophobia*. Then, there is the state of general *mental blindness*, when visual stimuli are seen but lose their meaning, and the similar specific disorder of word-blindness, or *alexia*, and, of course, the variety of visual hallucinations and illusions of the truly insane.

The most commonly detected impairments of vision in school children are farsightedness (*hyperopia*) and nearsightedness (*myopia*). The incidence of farsightedness in children entering school is high and decreases as they progress through school, largely because of increased efficiency in accommodation. Astigmatism, which is a structural difficulty resulting in blurred vision, can be corrected by glasses. Poor fusion and depth perception can be detected more easily than they can be corrected, as adequate methods of training the eye muscles have not yet been developed. Fusion difficulties caused by differences in visual acuity in the two eyes or by differences in the size and shape of the images of the two eyes can be corrected by glasses.

VOCATIONAL AGRICULTURE—See AGRICULTURAL EDUCATION; VOCATIONAL EDUCATION.

VOCATIONAL DIVISION OF THE UNITED STATES OFFICE OF EDUCATION. The Federal Board for Vocational Education, an independent administrative agency (not a part of any federal department) was established by Act of Congress, proved February 23, 1917, to administer the Smith-Hughes Act. (Public—No. 347—64th Congress. Senate Bill 703.) The latter is "An Act to provide for the promotion of vocational education: to provide for cooperation with the States in the promotion of such education in agriculture and the trades and industries; to provide for cooperation with the States in the preparation of teachers of vocational subjects; and to appropriate money and regulate its expenditure."

The duties of the Federal Board for Vocational Education are set forth in detail in the Act. They may be summarized briefly by stating that they call for close cooperation with the states in developing appropriate standards; working out plans of procedure; giving adequate supervision and administration at the federal level; undertaking surveys, investigations, analyses, and studies; furthering and improving vocational education; keeping accurate records of essential data; publishing or causing to be published studies and reports; and giving counsel and supplying leadership where needed in the public interest in vocational education.

The Smith-Hughes Act makes continuous appropriations to be expended in the states under State Plans for Vocational Education. The vocational education program under the Smith-Hughes Act was expanded by the George-Reed Act, the George-Ellzey Act, and the George-Deen Act.

The Federal Board for Vocational Education was also designed as the administrative agency for the Civilian Rehabilitation Act, as approved June 2, 1920, and as amended. By the latter act the federal government agreed to cooperate with the states in an extensive program of civilian rehabilitation. (See VOCATIONAL REHABILITATION.)

Under Executive Order No. 6166, of June 10, 1933, the functions and duties of the Federal Board for Vocational Education were transferred to the Department of the Interior.

These were assigned to the Commissioner of Education, on October 10, 1933.

A little less than six years later, the United State Office of Education was transferred to the Federal Security Agency. Thus the administrative functions of the Federal Board for Vocational Education were assigned to the Vocational Division of the United States Office of Education of the Federal Security Agency. The Federal Board for Vocational Education remains in an advisory capacity to the Commissioner of Education, under the designation *Federal Advisory Board for Vocational Education*. The latter is composed of the Secretary of Agriculture, the Secretary of Commerce, the Secretary of Labor, the Commissioner of Education, a representative of labor, and a representative of manufacturing and commercial interests.

The federally aided program of vocational education of less than college grade is administered, under the Commissioner, by the Assistant U. S. Commissioner of Education and his staff of administrative assistants. For administrative and supervisory purposes, there are four regions: (1) North Atlantic Region [13 states and the District of Columbia]; (2) Southern Region [12 states and Puerto Rico]; (3) Central Region [12 states]; (4) Pacific Region [11 states and Hawaii].

The Vocational Division has an Agricultural Education Service, a Trade and Industrial Education Service, a Home Economics Education Service, a Business Education Service, a Vocational Research and Statistical Service, Consultants in Vocational Education, Employer-Employee Relations, and Public Service Training, and an Occupational Information and Guidance Service.

The Division works with and through the various State Boards for Vocational Education, State Departments of Education, and State Directors of Vocational Education, including corresponding boards, departments and directors in Hawaii, Puerto Rico, and the District of Columbia. The state, insular, and District of Columbia staffs serve as coordinating agents or as liaison between the federal staff and the local city, district, or county organizations.

The Vocational Division recognizes clearly that the administration of the Smith-Hughes Act of 1917; the Civilian Rehabilitation Act

of 1920; and the George-Deen Act of 1938 constitute a cooperative enterprise, and that policy making for vocational education is likewise a cooperative function concerning the states and the United States Office of Education. A series of regional conferences in addition to many state and local conferences has been held each year since 1917, to work out policies, plans, and problems for all concerned. In such a cooperative manner, the *Statement of Policies for the Administration of Vocational Education* (Vocational Education Bulletin No. 1, Washington, D. C., U. S. Government Printing Office) was prepared in 1917, and revised in 1922, 1926, and 1937; in such a cooperative manner the Vocational Division is working with the states not only in the "regular" program of vocational education, but in the extensive program of vocational training for hemispheric security and strength. (See NATIONAL DEFENSE; VOCATIONAL EDUCATION.) F.T.S.

References.
United States Government Manual (United States Information Service, Washington, D. C., 1941).

Laws Relating to Vocational Education and Agricultural Extension Work, Compiled by Elmer A. Davis (United States Government Printing Office, Washington, D. C., 1941).

VOCATIONAL EDUCATION. In its broader sense, "vocational education" refers to life-experiences, education, and training, both direct and indirect, that fit one to carry on a socially useful vocation. In a more restricted sense, "vocational education" refers to specific, functional training for useful employment.

Vocational education or training (the words are often used interchangeably) is given to youth who are getting ready to enter a vocation of their selection; to youth who have entered employment, and who seek to advance in the employment of their choice; to adult workers who wish to increase their efficiency in the vocations they follow; and to youth and adults who need readjustment or conversion training because of unemployment brought on by technological change, or by changes resulting from war or post-war adjustments.

In the United States, vocational education of less than college grade is divided into the following major categories:

1. Agricultural education (*q.v.*), which fits for farming occupations.

VOCATIONAL EDUCATION

2. Trade and industrial education, which fits for occupations in mechanical, manufacturing, building trades and other trades such as beauty culture.

3. Home economics (*q.v.*) education, which fits for the responsibilities of homemakers, including child care, food, clothing, family relations, care of the sick, etc.

4. Distributive education (*q.v.*), which fits for occupations followed by workers directly engaged in merchandizing activities, or in direct contact with buyers and sellers. Distributive occupations do not include clerical occupations such as stenography, nor trade and industrial workers such as those engaged in transportation of goods.

Types of Classes. Classes may be either full-time, meaning classes operating at least 25 or 30 or more hours per week, or part-time. Part-time vocational schools or classes are conducted for persons who have entered employment and who attend school on less than a full-time basis. For example, apprentice training is a form of part-time education.

When individuals get vocational instruction that is supplemental to their employment, such training is of a *trade extension* nature. If the instruction prepares the learner for a job other than, and not closely related to, the one he follows, the training is of a *trade preparatory* nature.

Vocational classes of less than college grade may be federally aided if they are under public supervision and control, if they are taught by qualified teachers, if the housing and equipment and courses of study and other requirements of the State Plan for Vocational Education have been met. Privately operated classes, whether conducted for profit or not, need not meet the same standards unless there is legislation to that effect. There is such legislation in at least one state. Extensive programs of vocational education are carried out under private initiative. Some of this training is of a very high order. There are also many high-grade private trade schools. To illustrate, many employers give job training to apprentices, helpers, and more advanced employees.

Administration. Tax-supported vocational education of less than college grade is administered through the Vocational Division of the United States Office of Education (*q.v.*),

in cooperation with State Boards for Vocational Education, and through the latter in cooperation with thousands of local boards of education.

All of the states, the District of Columbia, Puerto Rico and Hawaii have state, district, or insular plans for vocational education, drawn up in harmony with the provisions of the national vocational education acts and with the policies governing vocational education as drawn up cooperatively by representative federal, state, and local leaders in the field and set forth in Bulletin No. 1 (revised) of the U. S. Office of Education.

For purposes of federal supervision and administration, the United States is divided into four regions, each containing about 12 States, and each in charge of a regional agent and often one or more assistants, working out of Washington, D. C. There are regional and special agents representing the U. S. Office of Education in each of the four major fields of vocational education. The states and insular possessions also have supervisory staffs in each of the major fields who serve in a liaison or coordinating capacity between the federal and the local staffs.

Vocational schools may operate on a local, county, district, regional, or state basis.

More than 1500 state and local representative advisory committees on which labor and employers are equally represented help to determine policies, plan courses of study, recommend qualified teachers, help in selecting equipment, and assist the schools in other ways in making their work practical, functional, and in step with the requirements of today and the probable demands of tomorrow.

Financial Aid. Since vocational education is essential not only to local and state, but also to national and hemispheric security and welfare, the Federal Government has wisely provided substantial financial aid for vocational education at the secondary school level. This aid is provided through the Smith-Hughes Act of 1917 and the George-Deen Act of 1937. All of the Smith-Hughes funds and most of the George-Deen appropriations must be matched on a dollar-for-dollar basis by the states, or local communities, or both. The aid is granted only under carefully prescribed conditions that have been set up in order that the quality of the service rendered shall be safeguarded, and so that the funds

shall be used wisely for the purposes intended. (See FEDERAL AID TO EDUCATION.)

Vocational Technical Training. Technical training is training that involves an appreciable body of known facts or science. Most occupations have some scientific or technical content. For example, an artist must understand the technology of the colors he uses. Technical occupations, however, such as those of industrial, civil, mechanical, electrical, and chemical engineering, call for much scientific training.

The instruction given in all-day technical high schools or classes of the traditional sort is not considered vocational trade training. It is more in the nature of preparatory training for engineering. On the other hand, technical high schools may give technical training that is vocational as interpreted under the Smith-Hughes Act. If such schools prepare draftsmen, surveyors, laboratory technicians, technical inspectors, and the like at a level below that of degree granting institutions, without regard to meeting college requirements, and directly for employment, then such education is vocational in the sense mentioned.

Vocational technical education refers to any form of vocational education the purpose of which is to prepare for wage-earning employment in occupations of a scientific character which occupy an area between skilled crafts and the scientific professions. There is a strong demand in time of war as well as in peace-time for technicians and clinicians of many sorts who do not need four years or more of post high school training. This applies to the areas of agriculture and homemaking as well as to trade and industrial education.

The term *terminal technical training* appears to be especially suitable to describe these forms of technical education. It is being given in a variety of schools and classes, such as technical high schools, vocational schools, and junior colleges—both public and private.

Vocational Teacher Training. All states in the Union, the Insular Possessions, and the District of Columbia have accepted the provisions of the Smith-Hughes Act and the George-Deen Act. The former requires teacher training to be given, and the latter gives additional aid to teacher training in the

various major fields of vocational education. These fields are agricultural, trade and industrial, and homemaking (or home economics) education. The George-Deen Act also provides for training teachers of distributive education.

Such teacher training may be given directly by the State Department of Education, or may be offered by approved teacher education institutions. The courses may be accredited for teacher certification and they may also, under specified conditions, be accepted toward undergraduate and graduate degrees by colleges and universities.

Much vocational teacher training is being conducted for civilians and for personnel in the armed forces in connection with training for national defense and for victory on the battlefield.

Scope. The scope of vocational education at the secondary school level is much greater than commonly realized. Each of the four major fields is divided into many specializations and subjects of instruction. For example, farming is divided into cotton, general, self-sufficiency, animal-specialty, cash-grain, crop-specialty, part-time, unclassified, poultry, fruit, truck, and stock-ranch farming. In each of these, much specialized information and skill are required. (See AGRICULTURAL EDUCATION.)

Homemaking education covers many subjects of which the following are but examples: food for the family, clothing for the family, housing for the family, family finances, family and parental education, home decoration, home management, health and medical care of the family. Each of these may be subdivided into six or more specialized fields. (See HOME ECONOMICS.)

In trade and industrial education specialization is especially evident. A directory of federally aided all-day trade schools, published by the U. S. Office of Education in 1940, based on 1939 statistics, lists 167 trades. A few examples of such courses taught in public vocational schools are air conditioning, auto mechanics, aviation, boat building, cosmetology, dental mechanics, Diesel engines, electricity, graphic arts, instrument repairing, machine shop, neon tube lighting, photography, refrigeration, and welding. (See INDUSTRIAL ARTS EDUCATION.)

VOCATIONAL EDUCATION

Distributive education, too, includes many kinds of instruction. Representative topics are increasing sales to satisfied customers, store service, telephone service, delivery service, credit and collecting service, team work for store efficiency, training employees, buying merchandise, window displays, and advertising. (See DISTRIBUTIVE EDUCATION.)

As of June 30, 1941, more than 2,250,000 persons were receiving vocational education of less than college grade in the "regular" federally aided public schools. Approximately 2 million more men and women were receiving federally aided vocational training for national defense under programs operated with the cooperation of the U. S. Office of Education. These figures do not include the training given by many other public agencies, some of which are mentioned under "National Defense, Vocational Training for" (*q.v.*), nor private schools, agencies, or corporations.

With the passage of the National Vocational Education Act (Smith-Hughes) in 1917, vocational education was given nation-wide stimulation through federal grants to states which would inaugurate vocational education in the public schools. Such education was promoted in three areas, i.e., agriculture, home economics, and trades and industries, on a cooperative arrangement with the states. States were reimbursed out of federal funds on a population proportion plan, and the "matching principle" of providing state aid on the dollar-for-dollar basis was adopted. Later congressional acts—George-Reed and George-Ellzey — temporarily supplemented Smith-Hughes funds, and in 1936 the George-Deen Act provided for additional annual funds (subject to appropriation by Congress) and included distributive occupations as a new area for reimbursement. The text of these acts should be studied for detailed stipulations.

All states quickly took advantage of the opportunity to expand such vocational programs as were already in operation and to inaugurate new programs. Supervisory and advisory assistance is provided by the Vocational Education Division of the United States Office of Education. State supervision is supplied through state boards for vocational education and their staffs, and local administration is in the hands of school boards and

superintendents. Approximately \$22,000,000 of federal funds have been available for reimbursement each year under the above mentioned acts; this is much more than matched by state and local funds.

Agricultural Education. Agricultural education of secondary grade has expanded tremendously under the impetus of the federal acts. All states and territories now offer extensive programs of farmer training through the medium of the public schools. In 1942, 9,000 high schools employed vocational agriculture teachers and enrolled 331,000 high school students. The staffs of the United States Agricultural Education Service, of the state boards for vocational education, and of the teacher training institutions aggregate several thousand highly qualified men. In addition to the training of high school boys for proficiency in farming, vocational agriculture provides courses for out-of-school rural youth and for adult farmers. Young farmer courses enrolled 46,500 in 1942, and adult or evening schools were attended by 209,000 older farm operators.

The outstanding unique feature of vocational education in agriculture is the use of supervised practice as a device in learning. With the objective clearly accepted that the only education of value is that which functions effectively in the lives of the learner, students of vocational agriculture have the opportunity of putting into practice on their home farms, those abilities, both managerial and operative, which have been studied in the classroom by means of discussion, demonstration, and laboratory procedures. Each student selects, plans, carries on, records, and reports upon a supervised practice program consisting of productive and improvement projects and supplementary farm jobs, primarily for the purpose of consolidating his learning. In addition, of course, he "earns as he learns", for all such projects are practical farm enterprises and success is partially determined in terms of financial returns. The total net project income of agriculture students amounts to many thousands of dollars annually.

Vocational agriculture courses are formulated in terms of local community and student needs, and provide instruction in the production, feeding, breeding, housing, and management of livestock; the planting, culture,

and harvesting of crops; the conservation and utilization of soils; farm credit and other economic matters; and farm mechanics, including shop repair and construction, farm machinery and implements, farm power and tractors, farm building, roads, and fences, and farm home conveniences.

"The *Future Farmers of America* is the national organization of boys studying vocational agriculture in public secondary schools under the provisions of the National Vocational Education Acts." There were 245,822 on the active membership list as of June 30, 1942, representing "7,542 local Chapters of 47 States, Hawaii, and Puerto Rico". The primary purpose of this organization, as indicated in the statement of the secretary, "is the development of agricultural leadership, cooperation, citizenship, and patriotism".

Home Economics Education. Home economics education also has had a rapid growth since the enactment of the federal acts. In 1940-41, vocational programs in homemaking education were offered in 8,631 day schools, in which 10,129 teachers were employed and 545,408 high school students were enrolled; 244,746 were enrolled in 3,964 adult centers employing 5,105 teachers; and 81,737 were enrolled in 532 part-time schools employing 1,044 teachers.

Vocational education in home economics has for its ultimate objective the improvement of home and family life through the preparation of young people and adults for home living. To accomplish the above objective through instruction, students are taught how to achieve social, mental, and physical well-being as participants in the life of the families of which they are members.

Attention is given to the study of desirable family relationships and to the development of the personality; of the relationships of the family and its members to outside institutions; of the normal development and guidance of children; of definite instruction for a better understanding of physical needs—such as foods, clothing, and shelter—and the means of providing them under current conditions; and of the development of judgment in the wise use of resources, time, effort, and money in meeting home and family needs. Directed home experiences or home projects are considered a vital part of the program.

Trade and Industrial Education. In 1942, in the federally sponsored programs for trades and industries, 2,042 school systems employed 21,809 teachers and enrolled 850,597 students in day trade, part-time, and evening classes. In the day trade classes, pre-employment training, designed for regular high school students 14 years of age and over, is given in automobile mechanics, printing, machine shop, plumbing, carpentry, welding, electrical construction, radio, and similar skilled trades, in which they may earn as much as four units of credit. Evening classes enroll only employed workers 16 years of age and over, and provide instruction which is supplementary to their daily employment, for the purpose of improving their efficiency and earning capacity as workers. One-third of the money allotted to the states for trades and industries must be devoted to the education of young workers who can attend school only on a part-time basis. Although of perhaps minor significance, these classes enroll boys and girls 14 years of age and over and provide instruction designed to continue their general education and at the same time prepare them vocationally.

Diversified occupations is the newest development in the cooperative part-time program of industrial-vocational education. This program enrolls boys and girls of high school age, usually juniors and seniors, who are working part-time in shops, factories, stores, and offices. In this program, which is particularly well suited to the small community, the student learns the practical skills and job procedures of his occupation through practice on the job under the direction of his employer, and in the school he is given instruction in occupational studies and related subjects. These subjects are necessary for the intelligent understanding and practice of his occupation. In addition, he usually takes one or two academic subjects. A special teacher-coordinator teaches the occupational studies and coordinates the two phases of training. Local advisory committees consisting of representatives of employer and employee groups work with the school officials in planning the program.

Clearly, the most outstanding achievement of vocational-industrial education has been the program of training for war production workers. Since July, 1940, more than 5,000,-

VOCATIONAL GUIDANCE

000 workers have been trained in the school shops of the nation, involving an outlay of about \$200,000,000 of federal funds. In this program men and women of all ages and races, as well as many high school boys and girls, have been trained as welders, aircraft workers, machine operators, shipbuilders, and for other types of work essential to the war effort.

In this brief statement, it has been impossible to indicate special variations of practice that the new acts and new regulations have permitted. The national and state offices of education are able to provide information on all phases of vocational education.

VOCATIONAL GUIDANCE. The National Vocational Guidance Association holds that "Vocational guidance is the process of assisting the individual to choose an occupation, prepare for it, enter upon and progress in it. It is concerned primarily with helping individuals make decisions and choices involved in planning a future and building a career—decisions and choices necessary in effecting satisfactory vocational adjustments."

It is to be noted that the emphasis in the preceding definition is on self-activity with the counselor in a helping relationship; that the process of vocational guidance is a long-term one; and that vocational guidance takes place outside of, as well as in the school. In our fast-moving, complex and ever-changing life, vocational guidance, in its organized form, serves vitally essential functions. Through guidance young people find and retain their place of social and economic usefulness; through it adults are helped in the difficult tasks of war-time and post-war vocational adjustments. Intelligent, wisely ad-

ministered vocational guidance is a practical means of conserving human resources—as is vocational education, but in a different manner.

Vocational guidance and vocational education are interrelated, correlative functions. Vocational guidance is of help in selecting a vocation and in making adaptations as circumstances require, whereas in vocational education the individual is assumed to have selected his occupation. The emphasis in vocational guidance is on self analysis, counsel, information about occupations, working conditions and opportunities. Vocational education focusses upon making persons employable and efficient producers through developing occupational skills and related knowledge.

Illustrative of the correlative functions of vocational guidance and vocational education is the procedures of giving information about aircraft, how they are made, the materials and processes involved, the working conditions in aircraft manufacturing plants and in repair depots, and of selecting workers who have the interest, physical, mental, emotional and other traits needed in those aircraft plants and depots. Without specific, functional vocational training the guidance and selection efforts would fail to function. Aircraft workers are not produced by vocational guidance alone. On the other hand the management of aircraft plants does not wish to hire persons who have little or no interest in, and aptitude for, the work that must be done in their establishments. At this point good vocational guidance is of much practical value—it helps to find the right individuals for jobs as they are, and assists them in carrying on those jobs successfully.

Vocational guidance is not to be confused with the broader function of education. Neither is vocational guidance to be confused with other forms of guidance, such as school, curriculum, or educational guidance, recreational guidance, health guidance, and community service guidance.

Vocational guidance seeks to minimize the extensive losses annually resulting from persons entering and staying in occupations for which they are poorly suited. It is a major social obligation in a democracy to see to it that youth and adults are assisted through carefully planned, professionally

administered, socially inspired vocational guidance.

Vocational guidance functions through: (a) Vocational information service—giving individuals information about occupations through reading, discussion, interviews, visual-sensory aids, and other means. (b) Self-inventory service—teaching individuals how to study and assess their own aptitudes, abilities, interests, and ambitions. (c) Personnel data. (d) Counseling—this calls for an understanding of persons on the one hand, and of occupational life on the other. Counseling may precede employment, be given during employment, or take the form of adjustive service for individuals who may need to make occupational and other adaptations.

Effective guidance includes laying a sound background for selecting occupations, for placing individuals after they have had the necessary pre-employment training, for following them up to see that they succeed, and for suggesting supplementary or adjustive education when needed. (See GUIDANCE; VOCATIONAL EDUCATION.) F.T.S.

VOCATIONAL INFORMATION — See OCCUPATIONAL INFORMATION.

VOCATIONAL INTERESTS. It is a truism that the vocational interests of youth change with their educational, social, and economic insight. Courses in occupations, in vocational guidance, and in various forms of practical arts, as well as other exploratory courses, are useful in helping to determine and develop vocational or occupational interests.

There are a few helpful, though broad, standardized vocational interest tests. Among the best known as the "Vocational Interest Test for Men," and the "Vocational Interest Test for Women," developed by Dr. E. K.

Strong of Stanford University. Tests of this kind are useful in determining in what groups of related occupations or professions one has interest. For example, they may reveal that the examinee has a general aptitude for or an interest in teaching. However, they are not specific to the extent of indicating, for example, the subject or subjects for which he would have special qualifications or would most enjoy teaching.

Work experiences obtained under actual conditions of employment are valuable as an aid in determining vocational interests, but it is usually necessary to make a vocational choice before such experience can be obtained. (See also OCCUPATIONAL INFORMATION, PRACTICAL ARTS, INDUSTRIAL ARTS, and OCCUPATIONAL TESTS.) F.T.S.

VOCATIONAL REHABILITATION.

The first Federal act aimed at vocational rehabilitation was a direct outgrowth of the World War. The *Smith-Sears Act* of June 27, 1918, 40 STAT. 617, as amended July 11, 1919, 41 STAT. 158, was intended for the vocational rehabilitation of disabled soldiers, sailors, and marines who were unable to carry on gainful occupations. Suitable courses were provided; during the learning period, provision was made for the financial maintenance and support of the disabled veteran and his family.

Very soon after the passage of this act, attempts were made to broaden its scope to include all disabled persons; among such proposals was the *Smith-Bankhead Bill*, but no action was taken on it. The *Vocational Rehabilitation Act* of June 2, 1920 (41 STAT. 735, 29 U.S.C. 31-44) was broader in scope, applying to disabled civilians and providing "for the promotion of vocational rehabilitation of persons disabled in industry or otherwise and their placement in employment." Additional appropriations were provided in 1924, 1930, 1932, and the Act was extended to cover Hawaii in 1924, the District of Columbia in 1929, and Puerto Rico in 1931. The essential difference between the soldier and the civilian acts, apart from their coverage, was that the soldier act made rehabilitation a direct responsibility of the Federal government; while under the civilian act the States bore the direct responsibility.

Under the *Federal Emergency Relief Ad-*

VOCATIONAL SUBJECTS

ministration' (FERA), which was established in 1933, some funds were set aside for vocational rehabilitation in the States.

The program was put on a permanent basis through the adoption of the *Social Security Act* of August 14, 1935 (49 STAT. 633, 42 U.S.C. 301); appropriations were increased in 1939 (Sec. 53 STAT. 1381 Sec. 508).

By vocational rehabilitation is meant the procedure or process of fitting a disabled person for remunerative employment. The law defines a disabled person as "any person who, by reason of a physical defect or infirmity, whether congenital or acquired by accident, injury, or disease, is, or may be expected to be totally or partially incapacitated for remunerative occupation."

The Federal Vocational Rehabilitation Act is administered by the United States Office of Education, through a director of the Vocational Rehabilitation Division. This division works in cooperation with state boards of vocational education, and more particularly with state directors of vocational rehabilitation toward the two-fold purpose of bringing about the vocational reestablishment of persons with employment experience who have become unable to work at occupations because of permanent physical disability, and also to reestablish vocationally persons without employment experience who are permanently physically handicapped and whose opportunities for employment are materially reduced because of such disability.

A distinction is drawn between persons who get medical, surgical, and other restorative service which does not result in employment, and vocational rehabilitation which does. Physical restoration may, however, be a part of vocational rehabilitation. There must be a return to, or establishment in, employment.

In order to cooperate with the federal plan, the State must (a) accept the provisions of the Federal Vocational Rehabilitation Act, (b) cooperate with the Office of Education in the administration of the Act, (c) prepare a state plan of cooperation between State workmen's compensation agency and the State Board for Vocational Education administering the program, (d) arrange for the financial support and supervision of the program, and (e) appoint the state treasurer as

custodian of the federal funds allotted to the state for rehabilitation purposes.

The state rehabilitation staffs consist of a state supervisor or director, district supervisors or directors, and agents who are often known as case workers, field agents, or assistant supervisors. The various state and district offices may have stenographic and other office workers. "Case records" are kept which contain much essential information about each person—the result of careful diagnosis.

At the outset, it must be determined whether or not physical restoration is necessary. Competent specialists, such as orthopedic surgeons, determine this. When physical restoration is likely to be beneficial, such service may constitute the first step. Following this a suitable occupational objective is determined. This is followed by training—either "on the job" or in public or private schools suited to the purpose. In some cases training is given through correspondence schools, extension classes, vocational schools, and technical schools. When training is given "on the job" care must be exercised that exploitation of the trainee does not result. In fact that might also happen in some schools. The state supervisor and field staff work to prevent this abuse.

Placement and follow-up service, and retraining if necessary after placement, are essential features. The test of the effectiveness of the service rendered is measured objectively by improved earning capacity, but the feeling of satisfaction that comes to those who have been helped through rehabilitation to earn their living is an even more valuable, though less easily measured, result of vocational rehabilitation. WASHINGTON, BOOKER T. (c. 1859-1915). Booker T. Washington ranks among the most influential American educational leaders. Washington, a mulatto born into slavery, was educated at Hampton Institute where he accepted General Samuel Chapin Armstrong's educational and social philosophy. Armstrong emphasized character building, instruction in the agricultural, household, and other vocational skills, teacher training, and a missionary zeal for the improvement of the Negro race through practical education. Washington founded Tuskegee Institute in Alabama in 1880, and remained at its head until his death in 1915. Under his leadership Tuskegee developed a hospital and nurse-training school, teacher-training, industrial courses, and the household arts. Its influence extended not only into the outlying area but throughout the entire South. Washington himself became the dominant figure in Negro education during his lifetime; his influence continued long after his death.

When Washington began his work at Tuskegee, Negroes were in the throes of discouragement and disillusionment. The "restoration of white rule" in the South in 1877 seemed to make it all but impossible for them to continue their struggle for educational, social, and political advancement. On the basis of the practical educational program which Washington had familiarized himself with at Hampton and the exigencies of the situation at Tuskegee during its early years Washington formulated and promoted an educational and social philosophy which in many respects was new.

In his teachings at Tuskegee and in his speeches and writings, Washington minimized political power and race militancy and emphasized industrial training, character education, and the middle class virtues. He taught

the Negroes who came under his influence "to dignify and glorify common labor, and put brains and skill into the common occupations of life." Washington believed that racial prejudice against the black could be best broken down if the Southern white could be convinced that a program of industrial and practical education for the Negroes would enhance their economic value. In view of the fact that the ruling race controlled the very fate of the Negro, such a position was in many respects a realistic one. Washington warned white men that if they held the Negro in the gutter, they would have to stay in the gutter themselves in order to keep the Negro there. The astute leader at first said very little about the constitutional right of the Negro to vote. Gradually he took the position that if the educated, property-owning Negro made it clear he would cast his vote for the Democratic party, the party which was held in white circles to represent Southern interests, the Negro would be permitted to exercise his suffrage rights. To the Negroes themselves Washington urged the importance of learning the various industrial skills and acquiring the middle-class virtues of frugality, diligence, sustained effort, honesty, and usefulness. These skills and virtues, he insisted, would enable the blacks to become property-owners, to enter the ranks of business, in short, to succeed. Racial advancement was certain, Washington held, to result from the individual advancement of members of the race. On the rare occasions when Washington referred explicitly to the race question, which he thought must be "*lived* down, not *talked* down," he reiterated the sentiment expressed in his famous address at the Cotton States Exposition in Atlanta in 1895: "in all things that are purely social we can be as separate as the fingers, yet one as the hand in all things essential to mutual progress."

Thus Washington's social philosophy of education emphasized race and class cooperation, rather than militancy and antagonism,

and embraced for the Negro the characteristically American middle-class values of self-help, success through usefulness and character, the dignity of manual labor, and the doctrine of progress.

Within this general social philosophy Washington developed a definite educational outlook and technique. At Hampton he had learned many of the white man's ways and values through the work which he did to earn his way. In the early days at Tuskegee it was necessary for the students to construct buildings, grow, prepare, and cook their food, and provide for their other material needs. Thus it was natural for them to learn arithmetic by figuring the cost of constructing and painting a building, by measuring an acre of land, by estimating the cost of producing and preparing pork and potatoes. As the school developed such industries as brick-making, to meet its own and the community's needs, an opportunity was provided for studying the history of the practical arts. All these matters formed the basis for instruction in English composition. Washington early discovered the basic principle that education was far more meaningful to students if "it stuck close to the common and familiar things—things that concern the greater part of the people the great part of the time." By the necessity of the situation education at Tuskegee was problem-solving, a problem-solving which rested, not on artificially created devices, but on the compelling needs of existence. Washington's emphasis on the social and educational significance of purposeful training makes him a great, pioneer educational leader. He gave the world a practical example of "a broader and more generous conception of what education is and should be than it had had before."

When it became clear that the educational achievements of the Negroes did not in fact seem to soften the caste system, Washington's emphasis on patience, acquiescence, and optimism occasioned criticism among many younger Negroes. This criticism became more marked when it became apparent that the type of industrial training which Tuskegee provided was obsolete in view of the rapid development of mass production through machinery and in view of the discriminations, at the hands both of employers and trades unions, against the Negro in the new type of factory industry. The relatively little em-

phasis Washington put on esthetic experience and on the characteristic cultural contributions of the Negroes in their arts, songs, and dances, similarly met with criticism among militantly race-conscious Negroes. Still others resented the "educational machine" which Tuskegee and Washington represented, a "machine" so powerful that no Negro could expect advancement in many educational quarters without the stamp of approval of the dominant leader.

In spite of these criticisms, some of which were from many angles of vision valid enough, Washington's shrewd common sense and statesmanship, his skill in developing racial contacts at a time when this was difficult to do on any level of mutual respect, and his emphasis on the dignity of labor and the possibility of a better life for his people give him true greatness of stature. (See also NEGRO EDUCATION.) M.E.C.

WINNETKA PLAN. At Winnetka, Illinois, the standards for the various grades of the elementary school are defined, and each pupil progresses toward these standards at his own pace. The great majority of pupils

meet the standards at the usual time, and there is no skipping of grades. Since the work is individualized and recitations are not needed in the academic subjects, a teacher in the fourth grade may have a few pupils who have not quite completed the work of the third grade as well as some pupils who have already started on fifth grade assignments. A bright fourth grade child, who would be mal-adjusted socially if he were promoted to a fifth grade class, may be working on the assignments for the fifth grade, even though he is kept with the fourth grade children for the sake of his social adjustment. Likewise, a slow learner can be with his own social group in the fifth grade room but be doing fourth grade work. Some pupils finish the elementary school in less than the usual six years, though others may not finish for seven years.

The Winnetka plan operates as in any other school so far as club, dramatic, physical education, and other group activities are concerned. The individualized phases pertain to the tool or academic subjects, and take about one-half of the school day. The plan enables the school to adjust the child's rate of progress to his ability, without exposing him to the emotional problems attendant upon either failure and retardation or forced association with older children.

WOMEN TEACHERS—See **TEACHERS, STATUS OF.**

WOMEN'S COLLEGES. The history of higher education for women, dating back to a little more than a century ago, is brief in comparison with the history of colleges for men. The effort to provide college training for women has progressed against the obstacles of the traditional belief that no training beyond the rudiments of literacy was required for the work which women were destined to perform. This narrow concept of "women's place" was expressed not only by limited educational opportunity but by statutory disbarment from electoral rights until 1920.

Before 1920 college courses for women were, in the main, of two sorts: (1) courses patterned after those in men's colleges, ap-

parently with the purpose of demonstrating that "women could learn whatever men could learn"; and (2) courses designed to perfect the "gentler sex" in the practice of approved conventions, including the niceties of social etiquette. But with the opening of the door to equal participation in civic and political matters and with the increased participation of women in business and the professions came the inevitable pressure for a type of education suited to women's broadening activities. As a result, education for civic and professional fields developed more rapidly than education for the already established needs of home, family, and community life. Only in recent years has there been any marked recognition of the need of training for the responsibilities of marriage and home-making.

Elementary training, including the fundamental skills of language and of numbers, has, of course, long been available to girls as well as to boys. Even the opportunities of secondary training, which is largely an extension of the basic subjects, were claimed by women from the beginning of the history of the American public high school. But "higher education," the education provided by the college, was for more than a century after the founding of the first colleges in America education of a highly specialized character concerned primarily with the traditional preparation for professional pursuits. Although the changed status of women has opened the doors of professional training to them, the focus of attention in developing the college program for women must remain fixed on the broader aspects of women's responsibility, namely the responsibility for competent guidance and direction of the life of the home and the community. In other words, educational programs for women, while they may include unrestricted opportunity for vocational choice, will center largely in the field of general education.

Looking at the current trends in women's education, one sees a community of aims emerging: (1) to provide training which will satisfy the normal cultural and intellectual needs and interests of women in home and community activities, (2) to provide training which will make for greater personal competence and efficiency as an individual, (3) to provide for occupational needs and in-

terests to insure economic self-dependence and family security, and (4) to train for effective citizenship through an increased understanding of civic responsibilities and a more intelligent participation in the democratic processes of government.

To set up a curriculum pointed toward the realization of these objectives, a critical examination of women's activities (together with a broad survey of social needs) has been required. For practical purposes such an analysis is made on the basis of intelligent observation. A functional educational philosophy moves surely and unmistakably toward a curriculum that answers observable and recognized needs. But such philosophical observation should be supported by social and educational research. The most far reaching study of this sort was conducted by Dr. W. W. Charters in 1920 upon the assumption of his duties as Director of Research for Stephens College. This basic activities study clearly identified certain areas of interest and need, prominent among which were civic and social understandings, æsthetic appreciation, intelligent consumership, communicational ability, religion and ethical values, physical and mental health, home and family responsibilities, and vocational interests.

Obviously traditional subjects cut across many of these fields, but for better focusing of instruction a reorganization of subject matter is necessary. Divisional barriers between subjects must be broken down and integrating relationships established. In many cases the answer to this need has produced new basic courses, examples of which are the courses at Stephens College, Columbia, Missouri, in the Humanities, the generalized course in Communications, and other basic "area" courses. In many women's colleges a similar trend in the adaptation of the curriculum is evident.

Current trends in educational philosophy and in the interpretation of social needs are bringing closer together the curricula for women and the curricula for men in modern colleges. This does not mean that there is a reversion to the traditional academic curriculum of the 19th century but rather that a clear vision of democratic needs is actuating reforms in higher education for both men and women. Political equality, industrial participation, common character needs and values, and broadening occupational oppor-

tunities have operated to bring about a convergence of purpose in the total program of education for youth.

There will always be, however, a difference between the educational men and the educational needs of and a corresponding difference in the ways in which those needs can be fully met. These differences are due to inherent differences in nature and to ability of function. Equality does not identity. To educate women for their potential contribution, the educator must consider their basic psychological and characteristics, their predisposition to religious and æsthetic appreciations, peculiar responsibility as the mothers of young children, their position in the home and the community as the consumer-spender of more than eighty per cent of the wages and salaries of the nation, their responsibilities in health conservation and home management. Such considerations will always dictate a distinctive and significant emphasis in the subject matter of college courses designed for the education of women. The advantage of the separate college for women is that this emphasis can be and is more clearly evident. In the commonality of the subject matter of the coeducational class, the differentiating accent is lost, the individual application is neglected, even though the content of the course may be basically functional for all. J.M.W.

WORD ANALYSIS. Word analysis is a term which includes all methods of dividing a word into parts or considering its details as an aid in word recognition and in spelling. Some training in word analysis is a necessary supplement to the widely used

Methods which teach words as units by a recognition approach.

There are many techniques that are frequently employed in analyzing words. (1) Attention may be paid to the first letter or of a word and to the word's general shape or configuration, aided by the meaning context of the sentence. This technique, frequently and effectively employed by good readers, is used excessively by some children with much inaccuracy as a result. (2) Relationship to words already learned may be noted, as for example, a child is helped on the word *shell* by noting its similarity to *tell*. (3) Small familiar words may be found within larger unfamiliar words. Care must be taken not to over-emphasize this procedure because of the danger of interfering with consistent left-to-right habits of observation. (4) Specific differences between words that are frequently confused may be noted and emphasized. (5) Words may be analyzed phonically—by syllables, phonograms, or single letters.

A good reader knows and can use several methods of word analysis, so that if one procedure does not succeed on a particular word he is able to try another. Well-rounded instruction in reading should give the pupil versatility in word analysis. (See PHONICS; and READING, METHODS OF TEACHING.)

WORKBOOK. While it is impossible to make a satisfactory classification of all types of workbooks, most modern workbooks can be classified into the following three general types: (1) Those containing only practice exercises, achievement tests, diagnostic tests, and other types of exercises with space for the work in the booklets. This type is designed to be used for supplementary work independent of any particular textbook. (2) Those containing directions for study, exercises, tests, etc., designed for use with some particular textbook to supplement the text material, or to provide additional learning experiences for class or individual needs.

These usually provide space for pupil's work. (3) Those consisting of outlines of units designed to cover a given field without paralleling any particular textbook. These usually contain detailed directions for study, instructional aids, exercises, tests, references, etc., and space for the pupil's work.

It is difficult to determine the exact origin of the workbook as a teaching device. While laboratory manuals and pupil workbooks of the notebook type date back to the introduction of the laboratory sciences and the source method of studying history before 1900, the modern workbook seems to be the product of the emphasis, since 1900, upon individual needs and individual differences. During the period from 1900 to 1920, emphasis upon the development of the individual child and individual learning experiences centered attention upon plans for individualizing instruction. During this same time emphasis upon the objective measurement of abilities and skills resulted in the production of exercise pads and booklets designed to supplement the regular textbook and provide extra material needed for drill and other individual needs. These movements prepared the way for the flood of modern workbooks which have been produced in abundance since 1920.

There seems to be considerable difference of opinion among educators as to the value of the workbook as a teaching device.

According to its advocates, the workbook may be used (1) to supplement classroom exercises, (2) to give practice needed to perfect abilities and skill, (3) to test self-improvement and achievement, (4) to diagnose learning difficulties, (5) to provide for individual differences and interests, (6) to provide a record of work to motivate self-improvement, and (7) to provide for independent, individual work. Workbooks save time for the busy teacher who could not otherwise supply suitable supplementary material. Many workbooks provide standards for comparing records of achievement, which would not be available otherwise. Rightly used, a good workbook may be a valuable asset.

Wrongly used, the workbook may prove a handicap to effective learning. There is no substitute for teacher and pupil planning—there is danger that the workbook, being convenient, may systematize teaching and learning to such a degree that the personal, inspirational teacher-pupil relationship may

be lost, and that far from adapting learning to individual needs and interests, it may channel learning into one inflexible groove. If pupils are set to hunting up and copying answers there may be little real learning. Lack of adequate library facilities prevents effective use of some workbooks. The cost may be too great in proportion to the value received, unless the workbooks are used effectively.

Workbooks should be chosen with as much care as textbooks, with special attention to the needs of the particular class and the individual students.

WORKERS' EDUCATION. Three types of workers' education are represented in American institutions. They might be characterized as (1) education for the underprivileged, (2) union education, and (3) education in political ideologies. These types are of course never found in their pure form, but shade continuously into one another.

The first has been favored by certain leaders in the workers' education program of the Works Progress Administration (*q.v.*), and some of the scholarship committees of the labor colleges. Education for the underprivileged, which has the same basis as the adult education literacy program, implies that industrial workers who have not had the advantages of middle class Americans are entitled to have their education deficiencies remedied in adult life. Removing deficiencies ordinarily means teaching the elements of reading and writing, plus some materials suitable for use in union meetings. Emphasis is put on the fact that though the materials employ elementary academic skills, they are keyed to adult interests, particularly interests of workers in industry. Occasionally the argument about the necessity for remedial education is used by scholarship committees as a screen for securing money.

The second type, union education, has been subject to the limitations which shackled the labor movement at the time the educational movement gained momentum in the early 1910's. Social thinking in the American Federation of Labor focused on the idea that if a

union could control a job field by 100 per cent organization, the economic problems of its members would be solved. Many union leaders refused to see any relationship between the welfare of its union members on the one hand, and the welfare of unorganized workers, the political scene, or international affairs on the other. Education which followed on the heels of this thinking was concerned largely with aspects of how to run a union: public speaking, parliamentary procedure, collective bargaining. Occasionally it branched out into labor history and labor economics; but as it branched, students became fewer. Labor institutes or labor colleges (bearing no relationship to accredited institutions of higher learning) sprang up in large industrial centers. A workers' education bureau which began as an independent organization finally became a permanently supported part of the American Federation of Labor. It now promotes short institutes in conjunction with labor conventions, and gives other types of education service. A few organizations have developed programs of health education, drama, and recreation; and financed workers' centers. The International Ladies' Garment Workers' Union has had one of the most complete programs of this kind. Since the inauguration of the workers education program of the Works Progress Administration, more teachers have been available for all activities fostered by the unions. But this educational assistance has been of doubtful effectiveness because teachers are chosen largely from relief rolls. Some of the schools in the one time Affiliated Schools for Workers (now the American Labor Education Service) fit in this category. The Wisconsin School for Workers is one of the best of these, having a far-sighted program of economic and political education, and at the same time adhering to the fundamental principle that a genuine education movement must grow out of those organizations in which adults are already interested. There have been attempts to make consumer cooperation the subject of the economic education of labor, and co-operatives have gained support in some areas. However, far-sighted programs are the exception, not the rule; and the rule is a narrowly conceived education addressed to the organizational prejudices of business agents.

The third type of workers' education has flourished in schools (some in the Affiliated Schools for Workers) to spread special political ideologies, particularly the manifold phases of communist and socialist doctrine. Education in political ideologies is emphasized by several schools located both in New York and on the Pacific Coast, although some of these schools, such as Brookwood Labor College in New York and Commonwealth College in Arkansas, are not at present in operation. All these schools had their inception outside the labor movement proper, in the minds of so-called intellectual radicals. They were never able to secure full support of rank and file workers who looked on their political leanings with suspicion. Though these schools have often done a fine job, they have made the mistake of attempting to impose a philosophy on the labor movement, rather than assisting a philosophy to grow in the native soil.

By and large workers' education is prey to that disease of disjointedness which possesses much of organized public adult education. (See ADULT EDUCATION.) It is not yet recognized by labor leaders as an integral and a vital part of the labor movement; nor are its manifold activities directed toward any central goal. Such an obvious medium as the labor press, for instance, has apparently never been considered a part of a comprehensive educational pattern. Consequently, there is no great labor daily which can interpret a viewpoint both to the public and to the organized workers. Organized labor is still relatively incoherent on large national and international issues, attesting to a lack of education in the social sciences. It has been loathe to trust educational experts, assuming that they knew nothing of the practical problems of labor organization; and practical leaders with educational vision have been scarce in the labor movement.

Out of the activity in the general area of workers' education, two movements at the present time show promise of future educational strength. One is the attempt, primarily by the Congress of Industrial Organizations, to interpret the union viewpoint to the whole American public, particularly via radio. The other is the coalition movement initiated by the Farmers Educational and Cooperative Union of America to consolidate the thinking

of farm and labor groups. In at least one state the movement has taken the form of joint action through a legislative convention to secure legislation for farm, labor, and educational groups. Though conventions are common in the United States, this particular one was unusual. That it took place at all was the result of educational vision and planning which brought together such diverse elements as representatives of all the farm organizations, the state federation of labor, the parent-teacher association, the state education association, the railroad brotherhoods, and civic groups. On a national scale, the coalition movement of farm and labor groups is bringing about widespread cooperation on such issues as distribution of manpower. Of the two educational movements, this is by far the more important; for it is the nucleus of farm-labor-education planning on an international scale.

WORKS PROGRESS ADMINISTRATION, EDUCATIONAL WORK OF. The Works Progress Administration was born of the Federal Emergency Relief Administration by an Act of Congress in 1935 to provide a comprehensive plan for employing physically able relief clients on socially useful public works submitted by national, state, and local public agencies. On July 1, 1939, the Works Progress Administration was transferred to the Federal Works Agency and renamed Works Projects Administration (hereinafter called the W.P.A.). This agency was terminated by executive order of President Franklin D. Roosevelt on December 4, 1942, which called for its final elimination by February 1, 1943.

The educational work of the W.P.A. was built upon the program started under its early predecessor, the Federal Emergency Relief Administration. Its primary purpose was to provide employment for needy, unemployed teachers and others qualified to

WORKS PROGRESS ADMINISTRATION

teach adult classes. The secondary purpose was to develop a socially useful educational program of classes, which were designed:

(1) To provide for adults, unable to read and write English with the ability of an average fifth grade pupil, classes in Americanization and elementary school subjects, so they might become informed citizens able to contribute usefully to their state and country.

(2) To provide opportunities for special training in vocational fields for those persons out of a job or who wished to become more proficient in their chosen vocation.

(3) To make available to adults certain types of general education classes, suited to their needs and desires, which would fit them to be informed, self-respecting, socially useful citizens. Examples of this were the parent education (*q.v.*), workers' education (*q.v.*), and similar programs.

(4) To provide a type of preparatory vocational training for physically handicapped adults, which would fit them for positions by which they might become useful, self-supporting citizens.

(5) To provide opportunities in nursery schools taught by needy, unemployed teachers for children, ages 2 to 5, of needy, unemployed families, in order that the educational experiences thus derived would develop the physical and mental well being of these underprivileged children.

The administration of the educational program was vested in a director on the staff of the National Administrator of the W.P.A. program. The administration of the program within the states varied greatly. In some states a member of the staff of the state superintendent of schools was the directing head, responsible primarily to the superintendent and paid by the superintendent's office. In other states, the directing head was a person, sometimes politically chosen, who was responsible primarily to the state W.P.A. administrator. Theoretically, statewide educational projects were to be approved and sponsored by the state superintendent of schools, but in some cases other means were utilized.

As the program progressed, its direction and control fell more and more closely under the W.P.A. authorities, with a parallel decreasing interest in it on the part of public school boards and executives, who served as

local sponsoring agencies for the educational projects. Toward the close of the program, most of the better teachers had secured other public or private employment.

The educational program of the W.P.A. reached its peak in the number of students enrolled in the month of April, 1936 (1,853,601 enrollees and 42,543 teachers, an average of 44 enrollees per teacher), and its peak in the number of teachers employed in the month of March, 1935 (44,284 teachers and 1,725,093 enrollees, an average of 39 enrollees per teacher).

Among the general achievements of the educational program of the W.P.A. should be listed the following:

(1) The awakening of the public generally to the importance and significance of the comparatively new fields of adult education (*q.v.*) and the nursery school (*q.v.*).

(2) The acquisition of the elementary skills of reading and writing by virtually millions of previously illiterate adults.

(3) The vocational rehabilitation of many previously unemployed adults, some physically handicapped, who were enabled to qualify for jobs in private employment.

(5) The rehabilitation of many unemployed teachers who gained teaching experience of continuing value in whatever positions they later assumed.

(5) The training in the field of adult education acquired by thousands of teachers and executive and supervisory staff personnel who directed the programs.

(6) The development of underprivileged pre-school children in nursery schools along with the training of their parents in the care and handling of children.

The impetus given to progress in the field of adult education through this experimental program on a broad scale should, on the whole, be a favorable one over the years.

YEN, JAMES YANG-CH'U. (1894-). James Yang-Ch'u Yen, a pioneer and active leader of the mass education movement in China, was born in 1894 in the province of Hunan. He is a graduate of Yale University and took post-graduate work at Princeton University, where he received his M.A. degree. His interest in the education of the masses began at the time of World War I, when he served as secretary of the Y.M.C.A. with the Chinese Labor Corps in France. Most of the laborers in the corps had had no schooling and could neither read nor write. Charged with the task of providing an adequate program to improve their morale, Yen decided to give them some elementary instruction in the Chinese language. The initial efforts met with encouraging response from the workers, who were eager to learn. Yen wrote his own textbook and later, with the help of other educational leaders, published a simple Chinese newspaper called the *Chinese Laborer's Weekly*. In the course of a few months the workers were able not only to write letters to their relatives and friends in China, but also to read simple news dispatches.

Returning to China after the war, Yen devoted himself to further efforts in mass education. As Chairman of the Department of Popular Education of the National Y.M.C.A., he conducted surveys in various cities and towns, finally choosing the city of Changsha in Hunan province as the first experimental station. In the meantime, other educational experts in China had been making a careful selection of the most commonly used characters of the Chinese language. Based on these findings, a series of four textbooks known as "The People's Thousand-Character Lessons" was compiled by Yen and his associates. The books, using a vo-

cabulary of one thousand most commonly used characters, constituted a literacy course which could be mastered in four month's time, with a total of ninety-six hours of instruction.

The experiment was carried to other centers, and interest in the movement grew so rapidly that a national conference on mass education was convened at Peiping in the autumn of 1923. An outgrowth of the conference was the organization of the National Association of Mass Education Movement, with Yen as general secretary. From then on, the movement became nationwide in scope. Provincial governments as well as the national government have been paying increasing attention to what is now generally known as "popular education" or "adult education."

In 1928 Yen moved his headquarters to Tingshien in Hopei province. Attention was now given to the problems of the masses in a rural community. The objectives of education were broadened to include the reconstruction and betterment of rural life in its cultural, economic, health, and political aspects. After the outbreak of the war in 1937, the Tingshien station was abandoned and new experimental districts established in Hunan and Szechwan. Leadership is now provided by the National College of Rural Reconstruction in Eastern Szechwan, which has enlisted the support of many prominent leaders of popular education in China. Yen serves as secretary of the college's board of trustees. (See CHINA, EDUCATION IN.)
